**TITLE:** DETECTION OF NUCLEIC ACID DIFFERENCES
USING COMBINED ENDONUCLEASE CLEAVAGE
AND LIGATION REACTIONS

**INVENTORS:** Francis Barany, Weiguo Cao, Jianmin Huang, and Jing Lu

**DOCKET NO.:** 19603/3331 (CRF D-2634A)

# DETECTION OF NUCLEIC ACID DIFFERENCES USING COMBINED ENDONUCLEASE CLEAVAGE AND LIGATION REACTIONS

5      This application claims benefit of U.S. Provisional Patent Application Serial No. 60/250,435, filed December 1, 2000.

The present invention arose from research sponsored by the National Institutes of Health under Grant Nos. ROI-CA 65930 and ROI-CA 81467. The United States Government may have certain rights.

10

## FIELD OF THE INVENTION

The present invention relates to detecting nucleic acid differences using combined endonuclease ("endo") cleavage and ligation reactions.

15

## BACKGROUND OF THE INVENTION

### Detection of DNA Sequence Variation

20      There is a great need in both basic and clinical research to identify DNA sequence variations with high efficiency and accuracy. The current techniques for detection of such variation can be divided into two groups: 1) detection of known mutations or polymorphisms and 2) detection of unknown mutations or polymorphisms (also referred to as mutation scanning). A variety of effective

25      methods have been developed for detecting known mutations and polymorphisms and include techniques such as direct DNA sequencing, allele-specific oligonucleotide hybridization, allele-specific PCR, DNA arrays, and PCR/LDR. There are a variety of techniques for detecting unknown mutations, but their sensitivity and accuracy vary greatly.

30

### Comparison of High-Throughput Techniques to Identify Unknown Mutations in Clinical Samples.

Identifying unknown mutations in clinical samples presents similar

35      difficulties as screening for known mutations, as well as some novel complications. A mutation present in a tumor sample may represent as little as 15% of the DNA

sequence for that gene due to stromal contamination. Therefore, screens for unknown mutations require high sensitivity in order to identify low abundance sequence. Since most cancer genes contain multiple exons which may be altered, even for commonly mutated genes (e.g. PTEN), most assay results of a single exon will be negative.

5    However, by pooling samples together, the probability of finding a significant mutation in a given assay increases. In order to increase the capacity of a screen by pooling samples, the technique must have a high enough sensitivity to tolerate further mutation dilution which results from pooling. Further, for uncommon germline mutations, the ability to pool samples greatly improves the throughput of evaluating

10    large numbers of samples in multiple exons.

Other significant complications associated with screening for unknown cancer mutations are the need to: (i) Identify either frameshift, nonsense, or missense mutations, and (ii) distinguish missense mutations from germline (i.e. silent) polymorphisms. The latter is of great significance, because it is estimated that

15    polymorphisms exist approximately once every kb in the human genome. Wang, D. G., et al., Science, 280(5366):1077-82 (1998), Li, W. H., et al., Genetics, 129(2):513-23 (1991), Lai, E., et al., Genomics, 54(1):31-38 (1998), Nickerson, D. A., et al., Nat Genet, 19(3):233-40 (1998), Harding, R. M., et al., Am. J. Hum. Genet., 60(4):772-89 (1997), Taillon-Miller, P. et al., Genome Res., 8(7): 748-54 (1998), Halushka, M. K.,

20    et al., Nat. Genet., 22(3): 239-47 (1999), and Cargill, M., et al., Nat. Genet., 22(3):231-38 (1999). Separating out the apparently less interesting polymorphisms should significantly increase the efficiency in identifying informative mutations. Unfortunately, present methods of identifying additional low frequency mutations with clinical significance are restricted in their applications. Most methods to date

25    lack either the accuracy to discriminate or the sensitivity to be an efficient technique. As a result, there is an urgent need for a scanning method with the potential to identify precise mutations and with the sensitivity to analyze tumors or germline DNA in pooled samples.

30    *Direct Sequencing and Variation Detection Arrays.*

A variety of methods have been developed to scan for unknown mutations. Direct sequencing represents an ideal in that it can detect any mutation

and its position, although high throughput is costly. Gyllensten, U. B. et al., Proc. Natl. Acad. Sci. USA, 85(20): 7652-56 (1988), Hultman, T., et al., Nucleic Acids Res., 17(13):4937-46 (1989), Phear, G. A. et al., Methods Mol. Biol., 31:247-56 (1994), Rao, V. B., Anal. Biochem., 216(1):1-14 (1994), Kovach, J. S., et al., J. Natl. Cancer Inst., 83(14):1004-9 (1991). This method has low sensitivity which prevents an accurate analysis of pooled samples, and, in regard to solid tumor samples, the technique is vulnerable to stromal contamination. In blinded studies, direct sequencing was unable to identify 20% of K-*ras* mutations in microdissected tumor samples. This number is consistent with other studies in which 24% of p53 mutations in lung tumor samples were not identified. Ahrendt, S., et al., Proc. Natl. Acad. Sci. USA, 96:7382-87 (1999). When automated sequence analysis was performed on these same lung tumor samples, this false negative value rose to 32%. Ahrendt, S., et al., Proc. Natl. Acad. Sci. USA, 96:7382-87 (1999). These results reflect the limits of sensitivity associated with direct sequencing and further demonstrate the difficulty of automating this approach. If a sample is known to have a mutation in a specific area, then repeated attempts of direct sequencing should be able to identify the mutation and its position. Therefore, direct sequencing may have utility as a second step to identify the exact base changed in a gene region previously identified as containing a mutation.

Variation detection arrays (VDA) use standard hybridization microarrays to scan large sequence blocks in given genes. Despite the high scanning capacity levels, this approach has some characteristics that limits its utility. VDA is unable to detect all mutations and has particular difficulty in detecting frameshift mutations, for example in the BRCA2 and p53 genes. Ahrendt, S., et al., Proc. Natl. Acad. Sci. USA, 96:7382-87 (1996), Hacia, J. G., et al., Nature Genetics, 14(4): 441-47 (1999). Primer extension arrays also fail to detect slippage of mononucleotide repeat sequences. Syvanen, A. C. et al., Hum. Mutat., 3(3):172-79 (1994). High false positive rates of 11-21% have been observed using VDA. Halushka, M. K., et al., Nat Genet., 22(3):239-47 (1999). One consequence of direct hybridization that may account for these inaccurate results involves the disruption of secondary structure. A perfect match PCR fragment may assume a secondary structure that is not present in variant fragments. Since a secondary structure is usually energetically unfavorable

with respect to fragment/array hybridizations, the variant fragment may bind the perfect match complement on the array with higher binding affinity than the true perfect match fragment. Hacia, J., Nature Genetics (Supplement), 21:42-47 (1999). Such illegitimate hybridizations would produce a false positive signal. Direct

5    hybridization of mutation-containing PCR fragments to sequences on the array has the additional difficulty of simultaneously assaying sequence tracts with localized regions of both high G+C and A+T content. Hacia, J., Nature Genetics (Supplement), 21:42-47 (1999). Certain mutations within these tracts can significantly decrease the Tm and thus lead to false negative signals.

10

*Gel-Based Assays, Mismatch Cleavage Enzymes, and Protein Truncation Assays*

Other methods that are widely used to detect unknown mutations

15    resolve homoduplex and heteroduplex DNA based on their differing electrophoretic migration behavior. These methods include single-stranded conformational polymorphism (SSCP) (Suzuki, Y., et al., Oncogene, 5(7):1037-43 (1990), Makino, R., et al., PCR Methods Appl., 2(1):10-13 (1992), Hayashi, K., PCR Methods Appl., 1(1):34-38 (1991), Korn, S. et al., J. Clin. Pathol., 46(7):621-23 (1993)), denaturing-

20    gradient gel electrophoresis (DGGE) (Fahy, E., et al., Nucleic Acids Research, 25(15):3102-9 (1997), Fodde, R. et al., Hum. Mutat., 3(2):83-94 (1994), Guldberg, P. et al., Nucleic Acids Res., 22(5):880-81 (1994), Ridanpaa, M. et al., Hum. Mol. Genet., 2(6):639-44 (1993), Ridanpaa, M., et al., Mutat. Res., 334(3): 357-64 (1995)), constant denaturing capillary electrophoresis (CDCE) (Chen, J. et al., Environ. Health

25    Perspect, 3:227-29 (1994), Khrapko, K., et al., Nucleic Acids Res., 22(3):364-69 (1994)), dideoxy fingerprinting (ddF) (Sarkar, G., et al., Genomics, 13:441-43 (1992)), and restriction endonuclease fingerprinting (REF) (Liu, Q. et al., Biotechniques, 18(3):470-77 (1995)). A similar approach, denaturing high-performance liquid chromatography (DHPLC), also resolves homoduplex from

30    heteroduplex DNA but is based on separation by ion-pair reverse-phase liquid chromatography on alkylated nonporous (styrene divinylbenzene) particles. Underhill, P. A., et al., Genome Res., 7(10):996-1005 (1997). Although these techniques contain some very desirable characteristics, none of them are complete

with respect to both previously-discussed throughput and sensitivity. The techniques which can identify the position of the polymorphism (ddF and REF), are not applicable for evaluating low level mutations in pooled samples. The rest of these techniques tend to be rapid and can detect low level mutations, but they cannot

5    distinguish missense from silent polymorphisms. In addition, since these methods do not locate the position of the mutation, they are less compatible with follow up techniques such as direct sequencing.

A sophisticated approach for detecting frame-shifts or termination codons in the APC gene uses a coupled transcription translation assay referred to as

10   the protein truncation test. Powell, S. M., et al., Nature, 359(6392):235-37 (1992), Powell, S. M., et al., N. Engl. J. Med., 329:1982-87 (1993), Redston, M. S., et al., Gastroenterology, 108(2):383-92 (1995), Petersen, G. M., et al., Hum. Genet., 91(4):307-11 (1993), Su, L. K., et al., Cancer Res., 53(12):2728-31 (1993). This is currently the most robust approach for finding mutations which generate truncated

15   proteins in large genes; however, it does not detect missense mutations or polymorphisms. Polymorphisms may also be identified by cleavage of mismatches in DNA hybrids, such as DNA-RNA heteroduplexes via RNase A mismatch cleavage (Winter, E., Proc. Natl. Acad. Sci. USA, 82(22):7575-79 (1985), Perucho, M., et al., Cancer Cells, 7:137-41 (1989), Myers, R. M., et al., Science, 230(4731):1242-46

20   (1985)), as well as in DNA-DNA homoduplexes via chemical mismatch cleavage (CCM) (Cotton, R. G. H., et al., Proc. Natl. Acad. Sci. USA, 85:4397-401 (1988), Hansen, L. L., et al., "Sensitive and Fast Mutation Detection by Solid-Phase Chemical Cleavage", in PCR Primer: A Laboratory Manual, C. W. Diefenbach and G. S. Dveksler, Editors., Cold Spring Harbor Laboratory Press: New York. p. 275-86

25   (1995), Haris, I. I., et al., PCR Methods Appl., 3(5):268-71 (1994)), T4 Endonuclease VII or MutY cleavage (Youil, R., et al., Proc. Natl. Acad. Sci. USA, 92(1):87-91 (1995), Xu, J. F., et al., Carcinogenesis, 17(2):321-26 (1996), Giunta, C., et al., Diagn. Mol. Pathol., 5(4):265-70 (1996)), or via Cleavase. Recently, a plant endonuclease, CEL I, with similar activity to T4 endonuclease VII has been described. Oleykowski,

30   C. A., et al., Nucleic Acids Res., 26(20):4597-602 (1998). CEL I has similar activity to nuclease S1 and works at neutral pH. Its cleavage efficiency and background varies according to the mismatch and specific template examined, and further

evaluation of other templates (e.g. in GC-rich regions) is still required. The most
accepted mismatch cleavage approaches identify the approximate position of the
polymorphism by using T4 Endonuclease VII or MutY to cleave a heteroduplex of
normal and polymorphic substrate at a mismatch. Youil, R., et al., Proc. Natl. Acad.

5      Sci. USA, 92(1):87-91 (1995), Xu, J. F., et al., Carcinogenesis, 17(2):321-26 (1996),
Giunta, C., et al., Diagn. Mol. Pathol., 5(4):265-70 (1996). These enzymatic cleavage
approaches identify the approximate position of most polymorphisms; however, these
enzymes often nick matched DNA causing a high background noise. This high
background tends to limit their usefulness with respect to solid tumor studies.

10     The present invention is directed to overcoming the above deficiencies
in the art.

## SUMMARY OF THE INVENTION

15     One aspect of the present invention is directed to a method for
identifying a mutant nucleic acid sequence differing by one or more single-base
changes, insertions, or deletions, from a normal target nucleotide sequences. This
method involves blending: (1) a sample potentially containing the normal target
nucleotide sequence as well as the mutant nucleic acid sequence; (2) providing two

20     labeled oligonucleotide primers suitable for hybridization on complementary strands
of the target nucleotide sequence and the mutant nucleic acid sequence; and (3)
providing a polymerase to form a polymerase chain reaction mixture. The
polymerase chain reaction mixture is subjected to one or more polymerase chain
reaction cycles comprising a hybridization treatment where oligonucleotide primers

25     can hybridize to the target nucleotide sequence and/or the mutant nucleic acid
sequence, an extension treatment where the hybridized oligonucleotide primer is
extended to form an extension product complementary to the target nucleotide
sequence and/or the mutant nucleic acid sequence to which the oligonucleotide primer
is hybridized, and a denaturation treatment where hybridized nucleic acid sequences

30     are separated. After the polymerase is inactivated, the polymerase chain reaction
extension products are denatured and the polymerase chain reaction extension
products are annealed to form heteroduplexed products potentially containing the

normal target nucleotide sequence and the mutant nucleic acid sequence. An endonuclease, which preferentially nicks or cleaves heteroduplexed DNA at a location one base away from mismatched base pairs, is then blended with the heteroduplexed products to form an endonuclease cleavage reaction mixture. The endonuclease

5    cleavage reaction mixture is blended so that the endonuclease preferentially nicks or cleaves heteroduplexed products at a location one base away from mismatched base pairs. A ligase and the potentially nicked or cleaved heteroduplexed products are blended to form a ligase resealing reaction mixture. The ligase resealing reaction mixture is incubated to seal the nicked heteroduplexed products at perfectly matched

10   base pairs but with substantially no resealing of nicked heteroduplexed products at locations adjacent to mismatched base pairs. The products resulting from incubating the ligase resealing reaction mixture are separated by size or electrophoretic mobility, and the presence of the normal target nucleotide sequence and the mutant nucleic acid sequence target nucleotide are detected in the sample by distinguishing the separated

15   products resulting from incubating the ligase resealing reaction mixture.

Another aspect of the present invention relates to a method for identifying a mutant nucleic sequence differing by one or more single-base changes, insertions, or deletions from a normal target nucleic acid sequence. In this method, a sample potentially containing the mutant nucleic acid sequence but not necessarily the

20   normal target nucleic acid sequence, a standard containing the normal target nucleic acid sequence, two labeled oligonucleotide primers suitable for hybridization on complementary strands of the mutant nucleic acid sequence, and a polymerase are blended to form a first polymerase chain reaction mixture. The first polymerase chain reaction mixture is subjected to one or more polymerase chain reaction cycles which

25   includes a hybridization treatment, where the labeled oligonucleotide primers can hybridize to the mutant nucleic acid sequence, an extension treatment, where the hybridized oligonucleotide primer is extended to form an extension product complementary to the mutant nucleic acid sequence to which the oligonucleotide primer is hybridized, and a denaturation treatment, where hybridized nucleic acid

30   sequences are separated. The polymerase is then inactivated. The normal target nucleic acid sequence, the labeled oligonucleotide primers, and the polymerase are blended to form a second polymerase chain reaction mixture. The second polymerase

chain reaction mixture is subjected to one or more polymerase chain reaction cycles comprising a hybridization treatment, where the labeled oligonucleotide primers can hybridize to the normal target nucleic acid sequence, an extension treatment, where the hybridized oligonucleotide primer is extended to form an extension product

5    complementary to the normal target nucleic acid sequence to which the oligonucleotide primer is hybridized, and a denaturation treatment, where hybridized nucleic acid sequences are separated. The polymerase is then deactivated. The first and second polymerase chain reaction extension products are denatured and then annealed to form heteroduplexed products potentially containing the normal target

10    nucleic acid sequence and the mutant nucleic acid sequence. An endonuclease which preferentially nicks or cleaves heteroduplexed DNA at a location one base away from mismatched base pairs is blended with the heteroduplexed products to form an endonuclease cleavage reaction mixture. The endonuclease cleavage reaction mixture is incubated so that the endonuclease preferentially nicks or cleaves heteroduplexed

15    products at a location one base away from mismatched base pairs. A ligase and the potentially nicked or cleaved heteroduplexed products are blended to form a ligase resealing reaction mixture which is incubated to seal the nicked heteroduplexed products at perfectly matched base pairs but with substantially no resealing of nicked heteroduplexed products at locations adjacent to mismatched base pairs. The products

20    resulting from incubating the ligase resealing reaction mixture by size or electrophoretic mobility are separated, and the presence of the normal target nucleic acid sequence and the mutant nucleic acid sequence target nucleotide in the sample is detected by distinguishing the separated products resulting from incubating the ligase resealing reaction mixture.

25                Another aspect of the present invention relates to a thermostable endonuclease which generates ends that are suitable for ligation when nicking perfectly matched DNA and preferentially nicks or cleaves heteroduplexed DNA as follows: (1) at a location where base pairs are mismatched or one base beyond the mismatch and (2) at A/A, G/G, T/T, A/G, A/C, G/A, G/T, T/G, T/C, C/A, or C/T

30    mismatched base pairs at a location where the base pairs are mismatched or one base beyond the mismatch. In each of alternatives (1) and (2), ends are generated which are suitable for ligation when nicking perfectly matched DNA. A thermostable

endonuclease in accordance with the present invention preferentially nicks or cleaves

at least one heteroduplex formed for any single base mutation or polymorphism,

except those having gRcg, rcRc, cgYc, or gYgy sequences, where the position of the

mismatch is underlined and shown in upper case, and generates ends which are

5      suitable for ligation when nicking perfectly matched DNA. Alternatively, the

thermostable endonuclease, which preferentially nicks or cleaves heteroduplexed

DNA, contains one, two, and three base insertions or deletions, at a location where the

base pairs are mismatched or one base beyond the unpaired bases, and generates ends

which are suitable for ligation when nicking DNA at perfect matched DNA.

10      Another aspect of the present invention is a mutant endonuclease V

("endo V") from *Thermotoga maritima* containing either: (1) a Y80A residue change;

(2) a Y80F residue change; (3) either a Y80L, Y80I, Y80V or Y80M residue change;

(4) an R88A residue change; (5) an R88L, R88I, R88V, or R88M residue change; (6)

an R88K residue change; (7) an R88N or R88Q residue change; (8) an R88D or R88E

15      residue change; (9) an R88T or R88S residue change; (10) a E89A residue change;

(11) a E89L, E89I, E89V, or E89M residue change; (12) a E89D residue change; (13)

a E89N or E89Q residue change; (14) a E89R or E89K residue change; (15) a E89T

or E89S residue change; (16) a H116A residue change; (17) a H116L, H116I, H116V,

or H116M residue change; (18) a H116K or H116R residue change; (19) a H116N or

20      H116Q residue change; (20) a H116T or H116S residue change; (21) a K139A

residue change; (22) a K139L, K139I, K139V, or K139M residue change; (23) a

K139R residue change; (24) a K139N or K139Q residue change; (25) a K139D or

K139E residue change; (26) a K139T or K139S residue change; (27) a D43A residue

change; (28) a D43E residue change; (29) a D105A residue change; (30) a D105E

25      residue change; (31) an F46A residue change; (32) an F46Y residue change; (33) an

F46L, F46I, F46V, or F46M residue change; (34) an R118A residue change; (35) an

R118L, R118I, R118V, or R118M residue change; (36) an R118K residue change;

(37) an R118N or R118Q residue change; (38) an R118D or R118E residue change;

(39) an R118T or R118S residue change; (40) a F180A residue change; (41) a F180Y

30      residue change; (42) a F180L, F180I, F180V, or F180M residue change; (43) a G83A

residue change; (44) a G83L, G83I, G83V, or G83M residue change; (45) a G83K or

G83R residue change; (46) a G83N or G83Q residue change; (47) a G83D or G83E

residue change; (48) a G83T or G83S residue change; (49) an I179A residue change; (50) an I179K or I179R residue change; (51) an I179N or I179Q residue change; (52) an I179D or I179E residue change; (53) an I179T or I179S residue change; (54) a D110A residue change; or (55) an H125A residue change.

5        A further aspect of the present invention is directed to a mutant endonuclease V which preferentially nicks or cleaves at least one heteroduplexed DNA, containing mismatched bases, better than a wild-type endonuclease V.

A further aspect of the present invention is directed to a method for identifying a mutant nucleic acid sequence differing by one or more single-base

10      changes, insertions, or deletions, from a normal target nucleic acid sequence. In this method, a sample potentially containing the normal target nucleic acid sequence as well as the mutant nucleic acid sequence, two labeled oligonucleotide primers suitable for hybridization on complementary strands of the target nucleic acid sequence and the mutant nucleic acid sequence, and a polymerase are blended to form a polymerase

15      chain reaction mixture. The polymerase chain reaction mixture is subjected to one or more polymerase chain reaction cycles comprising a hybridization treatment, where oligonucleotide primers can hybridize to the target nucleic acid sequence and/or the mutant nucleic acid sequence, an extension treatment, where the hybridized oligonucleotide primer is extended to form an extension product complementary to

20      the target nucleic acid sequence and/or the mutant nucleic acid sequence to which the oligonucleotide primer is hybridized, and a denaturation treatment, where hybridized nucleic acid sequences are separated. After the polymerase is inactivated, the polymerase chain reaction extension products are denatured and annealed to form heteroduplexed products potentially containing the normal target nucleic acid

25      sequence and the mutant nucleic acid sequence. An endonuclease which preferentially nicks or cleaves heteroduplexed DNA at a location one base away from mismatched base pairs and the heteroduplexed products are blended to form an endonuclease cleavage reaction mixture which is incubated so that the endonuclease preferentially nicks or cleaves heteroduplexed products at a location one base away

30      from mismatched base pairs. A ligase and the potentially nicked or cleaved heteroduplexed products are blended to form a ligase resealing reaction mixture which is incubated to seal the nicked heteroduplexed products at perfectly matched

base pairs but with substantially no resealing of nicked heteroduplexed products at locations adjacent to mismatched base pairs. A polymerase with 3'-5' exonuclease activity and the potentially nicked or cleaved heteroduplexed products are blended to form a polymerase exonucleolytic degradation reaction mixture which is incubated

5   under conditions effective for the 3'-5' exonucleolytic activity to remove several bases 3' to the nick. After the polymerase with 3'-5' exonuclease activity is inactivated, a polymerase without 3'-5' activity and the incubated polymerase degradation reaction mixture, labeled dideoxyterminator triphosphate nucleotides, and deoxyribonucleotide triphsophates are blended to form a polymerase mini-sequencing

10   reaction mixture which is incubated under conditions effective for the polymerase without 3'-5' activity to extend the 3' end of the nicked or cleaved heteroduplexed products to form mini-sequencing reaction products. The mini-sequencing products are separated by size or electrophoretic mobility, and the presence of normal target nucleic acid sequence and the mutant nucleic acid sequence are detected by

15   distinguishing the separated mini-sequencing products resulting from incubating the polymerase mini-sequencing reaction mixture.

The present invention has proven effective in identifying unknown frameshift, nonsense, and missense mutations as demonstrated in tests screening for various mutations in six genes associated with the development of inherited or

20   sporadic cancers. Furthermore, paired germline DNA can be evaluated side-by-side with tumor DNA, allowing this invention to even distinguish missense mutations from nearby or adjacent inherited polymorphisms. The assay also has broad applicability with respect to types of sequence variations that can be detected, and can identify 98% of the typical mutations or polymorphisms found in the human genome. In

25   addition, it is capable of scanning for mutations in a region as long as 1.7 kb or greater. The present invention can detect mutations in a high background of normal sequence. The present invention can detect a mutation or polymorphism in a 1:20 dilution with wild-type DNA and can even detect mutations/polymorphisms in cases as low as 1:50 dilution with wild-type DNA. This high sensitivity makes the present

30   invention amenable to pooled samples and, therefore, significantly increasing its throughput capabilities.

## BRIEF DESCRIPTION OF THE DRAWING

Figure 1 is a schematic diagram, illustrating the procedure for mutation scanning with the combination of *Thermotoga maritima* ("*Tma*") endoV and *Tsp.*AK16D DNA ligase.

Figures 2A-B show the purification of *Tma* endonuclease V. Figure 2A is a 12.5% SDS-PAGE, while Figure 2B shows gel filtration of the purified endoV. Molecular weight markers were from Sigma Chemical (St. Louis, MO). Ve is the elution volume and $V_0$ is the void volume.

Figures 3A-D show cleavage assays of *Tma* endonuclease V on double-stranded inosine-containing substrates. Figure 3A is an assay design where the top strand (SEQ. ID. No. 1) is Fam labeled and the bottom strand (SEQ. ID. No. 2) is Tet labeled to allow fluorescence detection on a GeneScan gel (Perkin Elmer). The positions of nucleotide changes at both strands are underlined. The length of the substrates and predominant products are marked. The cleavage sites are marked by arrows. The cleavage reactions were performed as described in M&M in the presence of 5 mM $MgCl_2$ with different E:S (enzyme : substrate) ratios. In Figure 3B, E:S = 1:10, and the relationship between substrate and product is shown by the arrow. In Figure 3C, E:S = 10:1 and the first lanes of Figures 3B and C are substrate negative controls. Figure 3D shows the location of cleavage sites. The length markers were synthetic oligonucleotides identical to the top strand or the bottom strand as shown in Figure 3A.

Figures 4A-B are plots of relative fluorescence intensity of cleavage products v. concentration of $MgCl_2$ which demonstrate the base-mismatch cleavage activity of *Tma* endonuclease V at varying concentrations of $Mg^{2+}$ or $Mn^{2+}$.

Figures 5A-D demonstrate the ability of *Tma* endonuclease V to cleave a variety of different single base mismatches in the presence of $Mg^{2+}$ or $Mn^{2+}$.

Figures 6A-B show the cleavage and binding of AP and uracil sites. Figure 6A shows the cleavage of double-stranded oligonucleotides containing a basic site (AP site) or deoxyuridine. 1: untreated substrate control; 2: AP substrates incubated at 95°C for 1 min in 50 mM NaOH as an AP site control; 3 and 10: oligonucleotide length markers; 4 and 7: 1 nM *Tma* endoV (E:S = :10); 5 and 8: 10

nM *Tma* endoV (E:S = 1:1); 6 and 9: 100 nM *Tma* endoV (E:S = 10:1. Figure 6B is a gel mobility shift assay of AP and uracil sites. Reactions were performed with 20 nM double-stranded oligonucleotide DNA substrates, 5 mM $CaCl_2$ and indicated amount of *Tma* endoV as specified below. Other buffer components are unchanged, 1:

5      substrate control; 2: 10 nM *Tma* endoV; 4 and 6: 100 nM *Tma* endoV; 7: inosine substrate control; 8: 100 nM *Tma* endoV with 20 nM inosine subtrate as positive control. Figures 6C-G show single stranded and nonspecific cleavage and binding by *Tma* endonuclease V. Figure 6C shows the cleavage of single-stranded oligonucleotides. Cleavage reactions were performed in the presence of 5 mM $MgCl_2$

10     or 1 mM $MnCl_2$ with 10 nM *Tma* endoV (E:S = 1:1). NS: non-specific sequence. Figure 6D shows the cleavage of plasmid substrate. Cleavage reactions were performed with 10 nM pFB76 plasmid in the presence of 5 mM $MgCl_2$ or 1 mM $MnCl_2$. Figure 26D shows the cleavage of AP site substrate (A/AP).

## DETAILED DESCRIPTION OF THE INVENTION

### Detecting DNA Sequence Differences

One aspect of the present invention is directed to a method for identifying a mutant nucleic acid sequence differing by one or more single-base changes, insertions, or deletions, from a normal target nucleotide sequence. This method involves blending: (1) a sample potentially containing the normal target nucleotide sequence as well as the mutant nucleic acid sequence; (2) providing two labeled oligonucleotide primers suitable for hybridization on complementary strands of the target nucleotide sequence and the mutant nucleic acid sequence; and (3) providing a polymerase to form a polymerase chain reaction mixture. The

polymerase chain reaction mixture is subjected to one or more polymerase chain reaction cycles comprising a hybridization treatment where oligonucleotide primers can hybridize to the target nucleotide sequence and/or the mutant nucleic acid sequence, an extension treatment where the hybridized oligonucleotide primer is

5    extended to form an extension product complementary to the target nucleotide sequence and/or the mutant nucleic acid sequence to which the oligonucleotide primer is hybridized, and a denaturation treatment where hybridized nucleic acid sequences are separated.  After the polymerase is inactivated, the polymerase chain reaction extension products are denatured and the polymerase chain reaction extension

10   products are annealed to form heteroduplexed products potentially containing the normal target nucleotide sequence and the mutant nucleic acid sequence.  An endonuclease, which preferentially nicks or cleaves heteroduplexed DNA at a location one base away from mismatched base pairs, is then blended with the heteroduplexed products to form an endonuclease cleavage reaction mixture.  The endonuclease

15   cleavage reaction mixture is blended so that the endonuclease preferentially nicks or cleaves heteroduplexed products at a location one base away from mismatched base pairs.  A ligase and the potentially nicked or cleaved heteroduplexed products are blended to form a ligase resealing reaction mixture.  The ligase resealing reaction mixture is incubated to seal the nicked heteroduplexed products at perfectly matched

20   base pairs but with substantially no resealing of nicked heteroduplexed products at locations adjacent to mismatched base pairs.  The products resulting from incubating the ligase resealing reaction mixture are separated by size or electrophoretic mobility, and the presence of the normal target nucleotide sequence and the mutant nucleic acid sequence are detected in the sample by distinguishing the separated products resulting

25   from said incubating the ligase resealing reaction mixture.

The first step of the invention is the preparation of heteroduplex nucleic acid fragments. In the preferred embodiment, genomic DNA containing both wild-type and the sequence variation(s) (e.g. single nucleotide mutations or polymorphisms, one or more nucleotide insertions, and one or more nucleotide

30   deletions) is PCR amplified with labeled oligonucleotide primers. Fluorescent, infrared, radioactive, or other labels may be used in the primers. In the preferred embodiment, *Taq* DNA polymerase or other PCR enzymes are inactivated, for

example, by digestion with proteinase K. The mixture of mutation or polymorphism containing and wild-type PCR fragments are denatured and then reannealed to form heteroduplex PCR fragments with nucleotide mismatches. In the preferred embodiment, denaturation is achieved by heating the fragments above their Tm value

5      (generally greater than 94°C), and reannealing is achieved by cooling first to 50-85°C, more preferably, 65°C for 5-30 minutes, more preferably 15 minutes, and then to room temperature for 5-30 minutes, more preferably 15 minutes, to form heteroduplex PCR fragments. Alternative means of denaturing/renaturing may be used. If wild-type genomic DNA is not known to be present in the original reaction, then

10     concurrently in a separate reaction, wild type genomic DNA is PCR amplified using the exact same primers as above. Equal molar amounts of mutation containing PCR fragments and wild type PCR fragments are mixed, heated, and then cooled to form heteroduplex PCR fragments with nucleotide mismatches.

The second step utilizes *Tma* endonuclease V for cleavage of the

15     heteroduplex DNA containing base mismatches. This reaction is preferably performed in an optimized reaction buffer at high temperature (50-65°C) for 30 minutes to 1 hour. Optimal buffer conditions include a neutral pH, low or no salt, and the presence of $Mg^{2+}$. Addition of organic solvents or other compounds, such as DMSO and betaine, may be used to facilitate cleavage by *Tma* EndoV. Use of

20     alternative conditions or metal co-factors (such as $Mn^{2+}$) may also facilitate cleavage. *Tma* endonuclease V activity can be sufficient even under sub-optimal conditions. The cleavage site was determined to be one nucleotide beyond the 3' position of the nucleotide mismatch.

For the next step, a supplemental buffer is added to bring the contents

25     and concentration of the buffer to a level optimized for a thermostable DNA ligase. In the preferred embodiment, a *Thermus* species ("Tsp.") AK16D DNA ligase is used. This ligation reaction is performed at 45 to 85°C, preferably 65 °C, for 2 to 60 minutes, preferably 20 minutes and utilizes the high specificity of Tsp. AK16D DNA ligase to reseal complementary nicks, while leaving cleaved mismatches unaltered.

30     This greatly reduces background and, therefore, dramatically increases the sensitivity of the assay.

In the fourth step, the cleaved fragments are separated, for example, by electrophoresis on a denaturing polyacrylamide gel or by capillary electrophoresis. Since the PCR primers of step one are labeled, fragments can be detected with the corresponding detection equipment. In the preferred embodiment, primers are

5      fluorescently labeled and detected using automated DNA sequencing or fluorescent fragment analysis instrumentation. The lengths of products are determined by comparison of the mobility of cleavage products to a fluorescent labeled molecular size standard. This allows for an approximate determination of the position of a mutation.

10     A second embodiment of this invention can incorporate a micro-sequencing method to determine which nucleotide is mutated. In preparing the PCR fragments, unlabeled primers are used in place of labeled primers, so that the heteroduplex PCR fragments are not fluorescent. After cleavage by *Tma* endoV and ligation by Tsp. AK16D ligase, *E. coli*. DNA polymerase I Klenow fragment is used

15     to excise several nucleotides from the 3' end of the nick generated by *Tma* endoV. Next, *Thermus aquaticus* ("Taq") DNA polymerase FS extends the shortened fragment using a mixture of fluorescent labeled dideoxynucleotides and unlabeled deoxynucleotides as substrates. This results in a short sequencing ladder from which the position and base of the variant nucleotide can be determined due to the mixed

20     signal of the normal and mutated nucleotide at the variant position.

Figure 1 is a schematic drawing illustrating the process of the present invention. In this drawing, the sample potentially contains a normal target nucleic acid sequence as well as a mutant nucleic acid sequence differing by one or more single-base changes, insertions, or deletions from the normal target nucleotide

25     sequence.

In the first step of this procedure, target DNA molecules in a sample, potentially containing wild type and mutant nucleic acid sequences are amplified by a polymerase chain reaction process. This involves denaturation of double stranded target DNA molecules to separate complementary strands from one another. Primers

30     with fluorescent labels F1 and F2 are then caused to hybridize to part of the target DNA molecule. In the presence of DNA polymerase and dNTPs, the primers are extended to form extension products which are complementary to a strand of the

target DNA molecule. After extension is completed, the hybridized nucleic acid
strands are separated from one another by a denaturation step. This cycle of
hybridization, primer extension, and denaturation is repeated until sufficient
amplification has taken place. Once this has occurred, PCR is terminated by

5     inactivating the polymerase and denaturing the hybridized nucleic acid strands.

        In the second step of Figure 1, the extension products formed by PCR
are annealed to one another to form heteroduplexed products. To the extent that these
extension products were formed in the first step of Figure 1 by extension of a primer
hybridized to a mutant nucleic acid sequence in the sample, the extension product will

10    include a mismatched base. As shown in the second step of Figure 1, the mismatch in
the extension product can be an A, C, T, or G nucleotide. When, in the second step of
Figure 1, an extension product produced by target nucleic acid sequence forms a
heteroduplex with an extension product produced by a mutant nucleic acid sequence,
there will be a mismatch in the heteroduplex. This lack of complementation between

15    such extension products is shown by a "bubble" where the extension products are
displaced from one another. Although not shown in Figure 1, homoduplexes
containing extension products produced solely from mutant nucleic acid (which
would usually be rare) or produced solely from the target nucleic acid sequence would
be fully complementary, so no bubble would form. The present invention is directed

20    to detecting the presence of such mutant nucleic acid sequences in the sample by
analyzing for mismatches in the heteroduplexes.

        The third step of Figure 1 involves subjecting the heteroduplexed
products to an endonuclease which preferentially nicks or cleaves the component
strands of the heteroduplexed products at a location one base away from a

25    mismatched base. In the case of heteroduplexed products which are formed from an
extension product produced by target nucleic acid sequence annealed to an extension
product produced by a mutant nucleic acid sequence as shown in the third step of
Figure 1, the component nucleic acid strands are nicked or cleaved one base away
from the bubble. As also shown in the third step of Figure 1, the endonuclease

30    cleaves these strands at non-specific cleavage sites where there is no mismatch. As to
the nicking which takes place at specific cleavage sites where there is a mismatch, the
endonuclease is generally very effective at making nicks in strands where the

mismatch base is an A or G, is less effective at making nicks where the mismatch base is T, and is generally ineffective at nicking where the mismatch base is C. This is shown in the third step of Figure 1 where nicking has occurred at the mismatched A, G, and T bases but not at the mismatched C base.

5          After endonuclease treatment is completed, the resulting potentially nicked or cleaved heteroduplexed products are treated with a ligase. As shown in the fourth step of Figure 1, the ligase reseals the nicked heteroduplexed products at perfectly mismatched bases. However, there is no resealing of the nicked heteroduplexed products at locations adjacent to where there is a mismatched base.

10          The products of the ligase resealing step are then separated from one another by size or electrophoretic mobility, usually by gel electrophoresis. The results of gel electrophoresis before treatment with either endonuclease or ligase, after treatment with endonuclease and treatment with ligase, and after treatment with both endonuclease and ligase is shown in Figure 1. As a result, cleavage products

15     produced due to the presence of mutant nucleic acid sequence in the sample are detected.

          In carrying out the process of the present invention, the sample can contain target nucleotide sequence which is either genomic DNA, DNA isolated from tumor samples, a double stranded cDNA copy of mRNA, or a PCR amplified DNA

20     fragment. In the sample being analyzed according to the process of the present invention, the molar ratio of the mutant nucleic acid sequence to the normal target nucleotide sequence is in a range of 1:20 to 20:1.

          The process of the present invention is capable of distinguishing an inherited or sporadic mutation or polymorphism from a polymorphism in the normal

25     target sequence. This distinction can be made in a tumor suppressor gene, oncogene, or DNA replication or repair gene. Such genes include Bcl2, Mdm2, Cdc25A, Cyclin D1, Cyclin E1, Cdk4, survivin, HSP27, HSP70, p53, $p21^{Cip}$, $p16^{Ink4a}$, $p19^{ARF}$, $p15^{INK4b}$, $p27^{Kip}$, Bax, growth factors, EGFR, Her2-neu, ErbB-3, ErbB-4, c-Met, c-Sea, Ron, c-Ret, NGFR, TrkB, TrkC, IGF1R, CSF1R, CSF2, c-Kit, AXL, Flt-1

30     (VEGFR-1), Flk-1 (VEGFR-2), PDGFRα, PDGFRβ, FGFR-1, FGFR-2, FGFR-3, FGFR-4, other protein tyrosine kinase receptors, β-catenin, Wnt(s), Akt, Tcf4, c-Myc, n-Myc, Wisp-1, Wisp-3, K-*ras*, H-*ras*, N-*ras*, c-Jun, c-Fos, PI3K, c-Src, Shc, Raf1,

TGFβ, and MEK, E-Cadherin, APC, TβRII, Smad2, Smad4, Smad 7, PTEN, VHL, BRCA1, BRCA2, ATM, hMSH2, hMLH1, hPMS1, hPMS2, or hMSH3.

Since residual active *Taq* DNA polymerase can extend EndoV cleaved DNA, PCR reactions can be incubated with proteinase K at 45 to 75°C for 5 to 60
5    min., preferably 70°C for 10 min. Subsequently, proteinase K is activated by incubating at 90 to 95°C for 10 to 60 minutes, preferably 70°C for 10 minutes. After amplification and proteinase K digestion, PCR fragments can be separated by agarose gel electrophoresis and visualized via ethidium bromide staining.

Most biological sources of target DNA will contain both variant
10   (mutation or polymorphism) and wild type DNA. In these cases, it is not necessary to add wild-type PCR fragments exogenously to the heteroduplex hybridization step. For example, if the substrate is genomic DNA containing a heterozygous germline mutation, only 50% of the PCR fragments will contain a mutation, while the other half will be of wild-type sequence. Therefore, it is not necessary to add wild-type
15   PCR fragments. Likewise, for solid tumor samples, there is typically a significant amount of stromal (i.e. wild-type) DNA within these samples. For sources of substrate in which a significant amount of endogenous wild-type DNA does not exist, an approximately equal amount of wild-type PCR fragments needs to be added. The optimal final ratio of mutant-to-wild type PCR fragments should be 1:1, although the
20   technique is compatible with other ratios of mutant-to-wild type PCR fragments.

The labeled oligonucleotide primers are labeled, preferably at their 5' ends. Useful labels include chromophores, fluorescent moieties, enzymes, antigens, heavy metals, magnetic probes, infrared dyes, phosphorescent groups, radioactive materials, chemiluminescent moieties, and electrochemical detecting moieties.

25   The polymerase is either a native or recombinant thermostable polymerase from *Thermus aquaticus, Thermus thermophilus, Pyrococcus furiosus,* or *Thermotoga maritima.*

The polymerase chain reaction process is fully described in H. Erlich, et. al., "Recent Advances in the Polymerase Chain Reaction," Science 252: 1643-50
30   (1991); M. Innis, et. al., PCR Protocols: A Guide to Methods and Applications, Academic Press: New York (1990); and R. Saiki, et. al., "Primer-directed Enzymatic Amplification of DNA with a Thermostable DNA Polymerase," Science 239: 487-91

(1988), which are hereby incorporated by reference. The polymerase chain reaction is initiated by adding either the polymerase or metal co-factors at temperatures of 65-94°C to the polymerase chain reaction mixture. The step of denaturing the polymerase chain reaction extension products is carried out in the presence of

5      proteinase K, preferably by heating to 80 to 105°C, preferably 94°C. The step of annealing the polymerase chain reaction extension products is carried out by cooling first to 50 to 85°C, preferably 65°C, for 5 to 30 minutes, preferably, 10 minutes and then to room temperature for 5 to 30 minutes, preferably, 15 minutes.

For heteroduplex DNA formation, the mixture containing fluorescently

10    labeled mutant and wild-type PCR fragments is denatured by heating at 93 to 100°C for 15 sec. to 5 min., preferably, 94°C for 1 min, thus rendering the DNA single-stranded. This is followed by a re-annealing step at 45 to 85°C for 2 to 60 min., preferably 65°C for 10 min, and, subsequently, incubating at room temperature for 5 to 30 min., preferably 15 min. After this process, theoretically 50% of the re-annealed

15    products are heteroduplex DNA containing a base-mismatch. An alternative reanneal step would be a slow cool from 95 to 25°C, decreasing the temperature by less than 1°C per minute, preferably, from 94 °C to 65 °C for 30-60 minutes. Alternative means of denaturing/renaturation of the DNA (such as treatment with a base followed by neutralization) may also be used. Typically, the polymerase chain reaction

20    extension products have a length in the range of 50 bp to 1,700 bp.

The endonuclease is preferably an Endonuclease V from *Thermotoga maritima*, *Aquifex aeolicus*, *Pyrococcus furiosus*, *Pyrococcus horikoshii*, *Pyrococcus abyssi*, *Pyrobaculum aerophilum*, *Archaeoglobus fulgidus*, *Aeropyrum pernix*, *Clostridium acetobutylicum*, or *Bacillus subtilis*. The endonuclease desirably nicks or

25    cleaves heteroduplexed products at a location on the 3' side one base away from mismatched base pairs. The endonuclease preferentially cleaves mismatches within the heteroduplexed products selected from the group consisting of A/A, G/G, T/T, A/G, A/C, G/A, G/T, T/G, T/C, C/A, and C/T. Alternatively, the endonuclease preferentially nicks or cleaves at least one of the heteroduplexed products formed for

30    any single base mutation or polymorphism, except those having a sequence selected from the group consisting of gRcg, rcRc, cgYc, and gYgy, where the position of the mismatch is underlined and shown in upper case. The endonuclease preferentially

nicks or cleaves one, two, and three base insertions or deletions within the heteroduplexed products.

The endonuclease cleavage reaction is preferably carried out in presence of $MgCl_2$ at a concentration of 2-7 mM or $MnCl_2$ at a concentration of 0.4-
5   1.2 mM. $MgCl_2$ should be added where the endonuclease to heteroduplexed product weight ratio in the endonuclease cleavage reaction mixture is in the range of 10:1 to 100:1; substantially no NaCl or KCl is present. Where the endonuclease to heteroduplexed product weight ratio in the endonuclease cleavage reaction mixture is in the range of 1:1 to 1:10, $MnCl_2$ should be added; in this case, a 25 to 75 mM,
10   preferably 50 mM, concentration of NaCl or KCl is present. Endonuclease cleavage can also be carried out in the presence of DMSO in a volume percent range of 2.5% to 10% and betaine in a concentration of 0.5M to 1.5M. Preferably, the endonuclease treatment is carried out at 65°C for 1 hour.

In the second step of the present invention, heteroduplexed PCR
15   fragments are cleaved by *Tma* endonuclease V. *Tma* endonuclease V contains unique properties that make it ideal for this process. Most significant is its ability to preferentially cleave one base beyond the 3' side of a mismatch and the fact that spurious nicks at complementary regions are suitable substrates for religation with DNA ligase. While there are other mismatch repair enzymes which are more efficient
20   in recognizing base mismatches, they generally do not cleave at the mismatch, nor do they leave ends suitable for religation. In conjunction with an appropriate ligase, these properties of *Tma* endo V allow for the reduction of background noise due to spurious nicking, while maintaining cleaved sites associated with mismatch sequence.

The third step of this invention seals nonspecific nicks in the
25   heteroduplex PCR fragments with a thermostable ligase, such as *Thermus* species AK16D, *Thermus aquaticus*, *Thermus thermophilus*, *Pyrococcus furiosus*, or *Thermotoga maritima*. The thermostable ligase may be derived from *Thermus aquaticus*. M. Takahashi, et al., "Thermophillic DNA Ligase," J. Biol. Chem. 259:10041-47 (1984), which is hereby incorporated by reference. Alternatively, it can
30   be prepared recombinantly. Procedures for such isolation as well as the recombinant production of *Thermus aquaticus* ligase as well as *Thermus themophilus* ligase) are disclosed in WO 90/17239 to Barany, et. al., and F. Barany, et al., "Cloning,

Overexpression and Nucleotide Sequence of a Thermostable DNA-Ligase Encoding

Gene," Gene 109:1-11 (1991), which are hereby incorporated by reference. These

references contain complete sequence information for this ligase as well as the

encoding DNA. Ligase resealing is preferably carried out in the presence of 50 mM

5    KCl to inhibit further endonucleolytic cleavage. Preferably, *Tsp* AK16D ligase is

used. Ligase resealing is carried out at a pH value between 7.2 and 7.8 when

measured at 25°C. Ideally, the cleavage of *Tma* endonuclease V should be inhibited

in this step. The optimal reaction buffer for *Tsp* AK16D ligase is 20 mM Tris-HCl

(pH 8.5), 5 mM $MgCl_2$, 25-75 mM (preferably, 50 mM) KCl, 10 mM dithiothreitol, 1

10   mM $NAD^+$, and 20 mg/ml BSA. See Tong, J., et al., Nucleic Acid Research 27:788-

94 (1999). As demonstrated in the Examples, *infra, Tma*. endo V is almost

completely inhibited in the presence of 50 mM NaCl or 50 mM KCl.

In order to obtain near optimal buffer conditions for the *Tsp* AK16D

ligse reaction., a supplemental buffer is added to the *Tma* endo V reaction. In a

15   preferred embodiment, the 10x supplemental buffer consists of 200 mM Tris-HCl (pH

8.5), 12.5 mM $MgCl_2$ , 500 mM KCl, 100 mM DTT, and 200 g/ml BSA. Typically,

15 µL of the reaction mixture from a *Tma* endonuclease V cleavage reaction, 2 µL of

10x supplemental buffer, 1 µL of 20 mM $NAD^+$, and 2 µL of 10-100 nM *Tsp* AK16D

ligase (stock enzyme solution) are combined. The mixture can then be incubated at 65

20   °C for 20 min and terminated by adding an equal volume of GeneScan stop solution

(50 mM EDTA, 1% blue dextran and 80% formamide).

The next step involves detection of the reaction products which can be

carried out using polyacrylamide gel electrophoresis or capillary gel electrophoresis.

In the preferred embodiment, the reaction mixture is denatured at 94°C

25   for only 1 minute (to avoid DNA fragmentation which can increase background

signal), and then cooled on ice. 2-3 µL of the mixture can then be loaded onto a 6%

denaturing polyacrylamide gel and electrophoresed for 1 hour. An ABI 377

sequencer (Perkin Elmer) at 1000 volt, 60 mA current, 200 W power, and a gel

temperature of 45°C can be used to separate and detect DNA products, although

30   alternative capillary or gel electrophoresis approaches can be used. Fluorescent

groups, 6-FAM (bottom fragment) and TET (top fragment), resolve blue and green,

respectively, in the ABI DNA 377 sequencer. The color of the cleavage band

indicates whether the cleavage product originated from the top or bottom strand.
TAMRA labeled GeneScan Molecular size standard 500 are loaded on the same gel.
This allows for the molecular weight of cleavage products to be estimated by
comparing the relative mobility of a cleavage product to the size standard. Preferably,

5     the GeneScan analysis software versions 2.1 or 3.0a (PE-Biosystems) is used,
although any state of the art gel-analysis software can instead be employed. This
analysis allows for the approximate site of the mutation to be determined.

Another aspect of the present invention relates to a method for
identifying a mutant nucleic sequence differing by one or more single-base changes,

10    insertions, or deletions from a normal target nucleic acid sequence. In this method, a
sample potentially containing the mutant nucleic acid sequence but not necessarily the
normal target nucleic acid sequence, a standard containing the normal target nucleic
acid sequence, two labeled oligonucleotide primers suitable for hybridization on
complementary strands of the mutant nucleic acid sequence, and a polymerase are

15    blended to form a first polymerase chain reaction mixture. The first polymerase chain
reaction mixture is subjected to one or more polymerase chain reaction cycles which
includes a hybridization treatment, where the labeled oligonucleotide primers can
hybridize to the mutant nucleic acid sequence, an extension treatment, where the
hybridized oligonucleotide primer is extended to form an extension product

20    complementary to the mutant nucleic acid sequence to which the oligonucleotide
primer is hybridized, and a denaturation treatment, where hybridized nucleic acid
sequences are separated. The polymerase is then inactivated. The normal target
nucleic acid sequence, the labeled oligonucleotide primers, and the polymerase are
blended to form a second polymerase chain reaction mixture. The second polymerase

25    chain reaction mixture is subjected to one or more polymerase chain reaction cycles
comprising a hybridization treatment, where the labeled oligonucleotide primers can
hybridize to the normal target nucleic acid sequence, an extension treatment, where
the hybridized oligonucleotide primer is extended to form an extension product
complementary to the normal target nucleic acid sequence to which the

30    oligonucleotide primer is hybridized, and a denaturation treatment, where hybridized
nucleic acid sequences are separated. The polymerase is then deactivated. The first
and second polymerase chain reaction extension products are denatured and then

annealed to form heteroduplexed products potentially containing the normal target nucleic acid sequence and the mutant nucleic acid sequence. An endonuclease which preferentially nicks or cleaves heteroduplexed DNA at a location one base away from mismatched base pairs is blended with the heteroduplexed products to form an

5      endonuclease cleavage reaction mixture. The endonuclease cleavage reaction mixture is incubated so that the endonuclease preferentially nicks or cleaves heteroduplexed products at a location one base away from mismatched base pairs. A ligase and the potentially nicked or cleaved heteroduplexed products are blended to form a ligase resealing reaction mixture which is incubated to seal the nicked heteroduplexed

10     products at perfectly matched base pairs but with substantially no resealing of nicked heteroduplexed products at locations adjacent to mismatched base pairs. The products resulting from incubating the ligase resealing reaction mixture by size or electrophoretic mobility are separated, and the presence of the normal target nucleic acid sequence and the mutant nucleic acid sequence target nucleotide in the sample is

15     detected by distinguishing the separated products resulting from incubating the ligase resealing reaction mixture.

### DNA Micro-sequencing for Identification of the Position and Composition of a Mutation or Insertion/Deletion.

20
A further aspect of the present invention is directed to a method for identifying a mutant nucleic acid sequence differing by one or more single-base changes, insertions, or deletions, from a normal target nucleic acid sequence. In this method, a sample potentially containing the normal target nucleic acid sequence as

25     well as the mutant nucleic acid sequence, two labeled oligonucleotide primers suitable for hybridization on complementary strands of the target nucleic acid sequence and the mutant nucleic acid sequence, and a polymerase are blended to form a polymerase chain reaction mixture. The polymerase chain reaction mixture is subjected to one or more polymerase chain reaction cycles comprising a hybridization treatment, where

30     oligonucleotide primers can hybridize to the target nucleic acid sequence and/or the mutant nucleic acid sequence, an extension treatment, where the hybridized oligonucleotide primer is extended to form an extension product complementary to the target nucleic acid sequence and/or the mutant nucleic acid sequence to which the

oligonucleotide primer is hybridized, and a denaturation treatment, where hybridized nucleic acid sequences are separated. After the polymerase is inactivated, the polymerase chain reaction extension products are denatured and annealed to form heteroduplexed products potentially containing the normal target nucleic acid

5    sequence and the mutant nucleic acid sequence. An endonuclease which preferentially nicks or cleaves heteroduplexed DNA at a location one base away from mismatched base pairs and the heteroduplexed products are blended to form an endonuclease cleavage reaction mixture which is incubated so that the endonuclease preferentially nicks or cleaves heteroduplexed products at a location one base away

10   from mismatched base pairs. A ligase and the potentially nicked or cleaved heteroduplexed products are blended to form a ligase resealing reaction mixture which is incubated to seal the nicked heteroduplexed products at perfectly matched base pairs but with substantially no resealing of nicked heteroduplexed products at locations adjacent to mismatched base pairs. A polymerase with 3'-5' exonuclease

15   activity and the potentially nicked or cleaved heteroduplexed products are blended to form a polymerase exonucleolytic degradation reaction mixture which is incubated under conditions effective for the 3'-5' exonucleolytic activity to remove several bases 3' to the nick. After the polymerase with 3'-5' exonuclease activity is inactivated, a polymerase without 3'-5' activity and the incubated polymerase

20   degradation reaction mixture, labeled dideoxyterminator triphosphate nucleotides, and deoxyribonucleotide triphosphates are blended to form a polymerase mini-sequencing reaction mixture which is incubated under conditions effective for the polymerase without 3'-5' activity to extend the 3' end of the nicked or cleaved heteroduplexed products to form mini-sequencing reaction products. The mini-sequencing products

25   are separated by size or electrophoretic mobility, and the presence of normal target nucleic acid sequence and the mutant nucleic acid sequence are detected by distinguishing the separated mini-sequencing products resulting from incubating the polymerase mini-sequencing reaction mixture.

Treatment with a polymerase with 3'-5' exonuclease activity is carried

30   out at a temperature of 20 to 40°C for 10 to 60 minutes, preferably 37°C and 30 minutes. Suitable polymerases with 3'-5' exonuclease activity are *E. coli* DNA polymerase I Klenow fragment, T4 DNA polymerase, and T7 DNA polymerase.

The polymerase without 3'-5' activity is utilized in the polymerase mini-sequencing reaction mixture at a temperature of 20 to 85°C for 10 to 60 seconds, preferably 60°C and 30 seconds. Suitable polymerases without 3'-5' activity are AmpliTaq DNA polymerase FS (Perkin Elmer, Foster City, CA), Thermo-sequenase,

5   (Amersham, Piscataway, NJ 08855), and DyNASeq, (M.J. Research, 590 Lincoln Street, Waltham, MA 02451). Examples of a mesophilic polymerases without 3' to 5' exonuclease activity are Sequenase (USB, Cleveland, OH 44128), and other polymerases with site-specific mutations to knock out the 3' to 5' exonuclease activity.

10      In this embodiment of the present invention, an optional DNA sequencing step (i.e. micro DNA sequencing) can be included to accurately determine the composition and position of an altered nucleotide. In this variation of the present invention, the procedure is similar to that described above, except that unlabeled PCR primers are used in the PCR reaction. This results in PCR fragments which are

15   unlabeled and, therefore, compatible with fluorescent dideoxysequencing. The presence or absence of fluorescent label is not an issue with radiolabeled dideoxy sequencing, and, therefore, the variation of the technique is purely one of compatibility with the detection method of the sequencing assay and not necessarily required for DNA sequencing in general.

20      The micro-sequencing strategy contains two additional steps. In the first added step, after the *Tma* endo V cleavage and ligation with *Tsp.* AK16D ligase, the 3' exonuclease activity of DNA polymerase I Klenow fragment is utilized to excise a few bases 3'→5' from the mismatch nick generated by *Tma* Endo V. *E. coli* DNA polymerase I Klenow fragment possesses approximately a hundred-fold lower 3'

25   exonuclease activity than T4 or T7 DNA polymerase (Sambrook, J. et al., Molecular Cloning-A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York (1989), which is hereby incorporated by reference). This allows for a more controlled removal of only a few bases. AmpliTaq DNA polymerase FS (Perkin Elmer) is then used to fill the resulting gap with a substrate

30   mixture of BigDye$^{TM}$ ddNTP/dNTP. This results in a very short fluorescent sequence ladder which can be analyzed to determine the exact position and nature of the variation.

**Mutants of *Thermatoga maritima* EndoV**

Another aspect of the present invention relates to a thermostable
endonuclease which generates ends that are suitable for ligation when nicking
perfectly matched DNA and preferentially nicks or cleaves heteroduplexed DNA as
follows: (1) at a location where base pairs are mismatched or one base beyond the
mismatch and (2) at A/A, G/G, T/T, A/G, A/C, G/A, G/T, T/G, T/C, C/A, or C/T
mismatched base pairs at a location where the base pairs are mismatched or one base
beyond the mismatch. In each of alternatives (1) and (2), ends are generated which
are suitable for ligation when nicking perfectly matched DNA. A thermostable
endonuclease in accordance with the present invention preferentially nicks or cleaves
at least one heteroduplex formed for any single base mutation or polymorphism,
except those having gRcg, rcRc, cgYc, or gYgy sequences, where the position of the
mismatch is underlined and shown in upper case, and generates ends which are
suitable for ligation when nicking perfectly matched DNA. Alternatively, the
thermostable endonuclease, which preferentially nicks or cleaves heteroduplexed
DNA, contains one, two, and three base insertions or deletions, at a location where the
base pairs are mismatched or one base beyond the unpaired bases, and generates ends
which are suitable for ligation when nicking DNA at perfect matched DNA.

Another aspect of the present invention is a mutant endonuclease V
from *Thermotoga maritima* containing either: (1) a Y80A residue change; (2) a Y80F
residue change; (3) either a Y80L, Y80I, Y80V or Y80M residue change; (4) an
R88A residue change; (5) an R88L, R88I, R88V, or R88M residue change; (6) an
R88K residue change; (7) an R88N or R88Q residue change; (8) an R88D or R88E
residue change; (9) an R88T or R88S residue change; (10) a E89A residue change;
(11) a E89L, E89I, E89V, or E89M residue change; (12) a E89D residue change; (13)
a E89N or E89Q residue change; (14) a E89R or E89K residue change; (15) a E89T
or E89S residue change; (16) a H116A residue change; (17) a H116L, H116I, H116V,
or H116M residue change; (18) a H116K or H116R residue change; (19) a H116N or
H116Q residue change; (20) a H116T or H116S residue change; (21) a K139A
residue change; (22) a K139L, K139I, K139V, or K139M residue change; (23) a
K139R residue change; (24) a K139N or K139Q residue change; (25) a K139D or

K139E residue change; (26) a K139T or K139S residue change; (27) a D43A residue change; (28) a D43E residue change; (29) a D105A residue change; (30) a D105E residue change; (31) an F46A residue change; (32) an F46Y residue change; (33) an F46L, F46I, F46V, or F46M residue change; (34) an R118A residue change; (35) an R118L, R118I, R118V, or R118M residue change; (36) an R118K residue change; (37) an R118N or R118Q residue change; (38) an R118D or R118E residue change; (39) an R118T or R118S residue change; (40) a F180A residue change; (41) a F180Y residue change; (42) a F180L, F180I, F180V, or F180M residue change; (43) a G83A residue change; (44) a G83L, G83I, G83V, or G83M residue change; (45) a G83K or G83R residue change; (46) a G83N or G83Q residue change; (47) a G83D or G83E residue change; (48) a G83T or G83S residue change; (49) an I179A residue change; (50) an I179K or I179R residue change; (51) an I179N or I179Q residue change; (52) an I179D or I179E residue change; (53) an I179T or I179S residue change; (54) a D110A residue change; or (55) an H125A residue change.

A further aspect of the present invention is directed to a mutant endonuclease V (and its above-described uses) which preferentially nicks or cleaves at least one heteroduplexed DNA, containing mismatched bases, better than a wild-type endonuclease V. Preferably, one of the mismatched bases in at least one of the heteroduplexed DNA is "A" or "G".

## EXAMPLES

**Example 1-    Reagents, Media, and Strains**

All routine chemical reagents were purchased from Sigma Chemicals (St. Louis, MO) or Fisher Scientific (Fair Lawn, NJ). deoxynucleotide, BSA, and ATP were purchased from Boehringer-Mannheim (Indianapolis, IN). Deoxyoligonucleotides were ordered from Integrated DNA Technologies Inc. (Coralville, IA). HiTrap SP columns were purchased from Amersham-Pharmacia Biotech (Piscataway, NJ).

Restriction enzymes, T4 DNA ligase and DNA polymerase I (Klenow fragment) were purchased from NewEngland Biolab (Beverly, MA). DNA sequencing kits, PCR kits, and GENESCAN-500 (TAMRA) Size Standard were

purchased from Applied Biosystems Division of Perkin-Elmer Corporation (Foster City, CA). *Pfu* DNA polymerase, PCR buffer and TaqPlus Precision PCR kit were purchased from Stratagene (La Jolla, CA). Protein assay kit was obtained from Bio-Rad (Hercules, CA).

5          FB medium (one liter) consisted of 25 gram Bacto tryptone, 7.5 gram yeast extract, 6 gram NaCl, 1 gram glucose, and 50 ml of 1 M Tris-HCl, pH 7.6. MOPS medium was prepared (as described in Neidhardt, F. C., et al., J. Bacteriol., 119(3):736-747) (1974), which is hereby incorporated by reference) as well as culture medium for enterobacteria. *Tma* endoV sonication buffer consisted of 20 mM

10    HEPES, pH 7.4; 1 mM EDTA, pH 8.0; 0.1 mM DTT; 0.15 mM PMSF; 50 mM NaCl. GeneScan stop solution consisted of 80% formamide (Amresco, Solon, Ohio), 50 mM EDTA (pH 8.0), 1% blue dextran (Sigma Chemicals). TB buffer (1x) consisted of 89 mM Tris and 89 mM boric acid. TE buffer consisted of 10 mM Tris-HCl, pH 8.0 and 1 mM EDTA.

15    Proteinase K was purchased from QIAGEN (Valencia, CA). Microcon 30 filters were purchased from Millipore (Bedford, MA). *Taq* DNA polymerase FS and four dideoxynucleotides were provided generously by PerkinElmer. Sep-Pak Cartridge C-18 was purchased from Waters (Milford, MA). Centri-Sep™ spin column P/N CS-90 was purchased from Princeton Separation (Adelphia, NJ).

20    Thermus species AK16D DNA ligase was cloned, overexpressed in *E coli.* and purified to homogeneity as described in Tong, J., et al., "Biochemical Properties of a High Fidelity DNA Ligase from *Thermus* Species AK16D," Nucleic Acids Res 27:788-94 (1999), which is hereby incorporated by reference.

25    **Example 2 -**    **Plasmid Construction, Cloning, Expression, and Purification of** ***Thermotoga maritima*** **Endonuclease V**

         Through BLAST searches (Altschul, S.F., et al., J. Mol. Biol., 215(3):403-10 (1990), which is hereby incorporated by reference), a putative open

30    reading frame of 225 amino acid has been identified in the *Thermotoga maritima* genome that shows 34% sequence identity to the *E. coli* endonuclease V gene. To prove that this, *Tma* ORF indeed encodes an endonuclease V, it was cloned and overexpressed in *E. coli.*

The putative endonuclease V gene (*nfi*) from *Thermotoga maritima* was amplified by PCR using forward primer EV.Tma.01A (5' GGA GGG AAT <u>CAT ATG</u> GAT TAC AGG CAG CTT CAC A 3' (SEQ. ID. No. 3), the *Nde*I site is underlined) and reverse primer EV.Tma.02R (5' GCG CCT <u>GGA TCC</u> <u>ACT AGT</u>

5     TCA GAA AAG GCC TTT TTT GAG CCG T 3' (SEQ. ID. No. 4), the *Spe*I and *Bam*HI sites are underlined). The PCR reaction mixture (100 µl) consisted of 50 ng of *Thermotoga maritima* genomic DNA, 10 µM of forward primer EV.Tma.01A, 10 µM of reverse primer EV.Tma.02R, 1 x *Pfu* PCR buffer, 100 µM of each dNTP, and 2.5 U *Pfu* DNA polymerase (Stratagene, La Jolla, California). The PCR procedure

10    included a pre-denaturation step at 95°C for 2 min, 25 cycles of two-step amplification with each cycle consisting of denaturation at 94°C for 30 sec and annealing-extension at 60°C for 6 min, and a final extension step at 72°C for 5 min. The PCR product was purified by routine phenol extraction and ethanol precipitation to remove thermostable *Pfu* DNA polymerase. Sambrook, J. et al., <u>Molecular</u>

15    <u>Cloning-A Laboratory Manual</u>, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York (1989), which is hereby incorporated by reference. The purified PCR product was digested with *Nde*I and *Bam*HI, and ligated to pEV1 vector digested with the same pair of restriction enzymes. pEV1 is a derivative of pFBT69 (Barany, F., <u>Gene</u>, 63:167-177 (1988), which is hereby incorporated by reference)

20    which contains an *Nde*I site after the Shine-Dalgarno sequence in the phoA promoter region and a downstream multiple cloning site (*Bam*HI-*Kas*I-*Bst*XI-*Eco*RV-*Eco*RI-*Mlu*I). The plasmid containing the putative *Tma* endonuclease V gene was designated as pEV5 and transformed into *E. coli* strain AK53 by a one-step protocol as described in Chung, C. T., et al., <u>Proc. Natl. Acad. Sci. USA</u>, 86(7):2172-75 (1989), which is

25    hereby incorporated by reference. The endonuclease V gene is regulated by a phoA promoter. The insert containing *Tma* endonuclease V gene was sequenced to ensure authenticity of the plasmid constructs.

    Overnight *E. coli* culture containing pEV5 was diluted 100-fold into FB medium supplemented with 50 µg/ml ampicillin. The *E. coli* cells were grown at

30    37°C with 200 rpm shaking to an absorbance at 550 nm of 0.8. The cultures were diluted 50-fold into 1 liter of MOPS medium supplemented with 50 µg/ml ampicillin, and grown under the same conditions overnight. After centrifugation at 3000xg for

10 min, the cell pellets were suspended in 10 ml of *Tma* endoV sonication buffer (20 mM HEPES, pH 7.4; 1 mM EDTA, pH 8.0; 0.1 mM DTT; 0.15 mM PMSF; 50 mM NaCl ) and sonicated on ice for two to three times at ten seconds each.

5     To purify the endonuclease V protein, cell debris were removed by centrifugation at 3000xg for 15 min. The supernatants were incubated at 70°C for 15 min to denature thermolabile *E. coli.* host proteins. After separating inactivated *E. coli* proteins by centrifugation at 10,000xg for 20 min, the supernatants were dialyzed against the starting buffer (50 mM HEPES, pH 7.4, 1 mM EDTA, 50 mM NaCl, 0.1 mM DTT) overnight.

10     Figure 2 shows a 12.5% SDS- PAGE gel demonstrating the purification of *Thermotoga maritima* endonuclease V protein at various stages in the process. Lane 2 shows the total proteins released from *E. coli.* cells. Since most *E.coli* host proteins are thermolabile, while *Tma* endoV is thermostable, the lysate was heated at 70°C for 15 min in order to inactive most *E. coli* host proteins 15 (including *E. coli.* endo V, See Example 4) while maintaining *Tma* endoV activity. After heat treatment, inactivated *E.coli* host proteins aggregate, and the majority of host proteins can be pelleted and removed by centrifugation. This leaves *Tma* endoV as the major protein in the supernatant, as demonstrated in Figure 2 Lane 3 which shows proteins in the supernatant after heat treatment and centrifugation. *Tma* 20 endonuclease V eluted at about the 24 kDa position, indicating that it exists as monomer in solution (Figure 2B).

*Tma* endonuclease V was purified to near homogeneity using a HiTrap SP column containing sulphopropyl functional group (Pharmacia). In a buffer at pH 7.4, *Tma* endonuclease V carries a net positive charge, making it a compatible 25 substrate for the HiTrap SP. The column was then either washed stepwise with elution buffers containing increasing amounts of NaCl, or washed with a buffer containing a NaCl concentration gradient in conjunction with an FPLC or HPLC system. Elution of a protein from the column is dependent on a particular NaCl concentration for that protein. In the stepwise elution, proteins were eluted with 150 30 mM NaCl to 500 mM NaCl at 50 mM interval. Pure *Tma* EndoV was eluted with 250-300 mM NaCl. Figure 2, lane 4 demonstates that the enzyme from the elution with 250-300 mM NaCl is nearly homogeneous. The concentration of the enzyme

was then determined by the ultraviolet absorption method: protein concentration=A(280)xOD 280. Wetlaufer, D.B., Adv. Prot. Chem. 17:303-390 (1962), which is hereby incorporated by reference. For *Tma* endoV, 1A=0.89 mg/ml, which was calculated by using the Protean software program (Power Macintosh

5    version 3.05, DNA Star Inc.) and based on the protein sequence of *Tma* endoV. The *Tma* endoV protein sequence (nfi gene) is available at the TIGR Microbial Database Locus TM1865 at web site: http://www.tigr.org/tdb/, under the section *Thermotoga maritima.*

       To ensure that the purified *Tma* endonuclease V as shown in Figure 2

10   is devoid of endogenous *E. coli* endonuclease V which has a similar molecular weight, the protein was transferred to a PVDF membrane and subjected to N-terminal sequencing according to the procedure used in Cao, W. et al., J. Biol. Chem., 273(49):33002-10 (1998), which is hereby incorporated by reference. The peptide sequencing result matched the predicted N-terminal sequence of *Tma nfi* gene.

15   Additionally, a 70°C-15 min heat-treatment was performed on *E. coli* endonuclease V purchased from a commercial source (Trevigen, Gaithersburg, MD). While the untreated enzyme was active as reported, the heat-treated enzyme lost its enzymatic activity. Thus, the heating step used in purification is likely to have inactivated *E. coli* endonuclease V

20

## **Example 3 - Oligonucleotide Substrates Preparation**

       *E. coli* endonuclease V demonstrates high activity with double-stranded DNA strands containing deoxyinosine-deoxyinosine or deoxyinosine-base

25   mismatch. Yao, M. and Kow, Y. W., J. Biol. Chem., 269(50):31390-96 (1994), which is hereby incorporated by reference. This general characteristic of endoV was used in order to functionally identify the purified *Tma* endoV enzyme. A double-stranded oligonucleotide containing a base mismatch was designed as a substrate to monitor for cleavage activity by the purified enzyme. Figure 3A shows a simple

30   assay system using two differentially labeled fluorescent oligonucleotides. The top strand is labeled with 6-FAM and the bottom strand is TET labeled. The mismatch position of the deoxyinosine nucleotide is off-center so that nicked products do not comigrate on a denaturing polyacrylamide gel. The differential double labeling

allows the nicking events on both strands to be easily observed and distinguished on the gel.

Oligonucleotide DNA substrates were purified on denaturing sequencing gels (7 M urea/10% polyacrylamide) as described in "The Complete
5     Guide: Evaluating and Isolating Synthetic Oligonucleotides" (Applied Biosystems Inc., Foster City, CA)). Purified oligonucleotides were dissolved in TE buffer. Equal molar concentration of two complementary single strands were mixed and incubated at 85°C for 3 min and allowed to form duplex DNA substrates at room temperature for 30 min.

10

## Example 4 - Cleavage of Deoxyinosine-Containing Oligonucleotides

In order to functionally identify the purified enzyme, deoxyinosine-containing substrates were initially used since *E. coli* endonuclease V shows high
15     activity toward an deoxyinosine-containing strand. Yao, M. et al., J. Biol. Chem, 269(50):31390-96 (1994), which is hereby incorporated by reference.

The cleavage reactions were performed at 65°C for 30 minute in a 20 µl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM MgCl2 unless otherwise specified, 10 nM DNA substrate, and the indicated
20     amount of purified *Tma* endonuclease V protein. The reaction was terminated by adding an equal volume of GeneScan stop solution. The reaction mixtures were then heated at 94°C for 2 min. and cooled on ice. Three microliter samples were loaded onto a 10% GeneScan denaturing polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an ABI 377 sequencer (Perkin Elmer).
25     Cleavage products and remaining substrates were quantified using the GeneScan analysis software versions 2.1 or 3.0.

At a low enzyme concentration (E:S = 1:10, S = 10 nM, E:S stands for the ratio of enzyme-to-substrate, S stands for substrate), *Tma* endonuclease V nicked exclusively at deoxyinosine-containing strands regardless of whether deoxyinosine
30     was placed on the top or bottom strand or both (Figure 3B). Cleavage was efficient for all four kinds of deoxyinosine base-pair (I/A, I/G, I/C, I/T), confirming a previous observation with the *E. coli* enzyme. Yao, M. et al., J. Biol. Chem, 269(50):31390-96 (1994), which is hereby incorporated by reference. The predominant products were

formed by nicking at the 3' side one nucleotide after the inosine base on both strands (Figure 3D). At a high enzyme concentration (E:S = 10:1, S = 10 nM), *Tma* endonuclease V nicked deoxyinosine-containing strands effectively, resulting in virtually complete conversion to nicked products (Figure 3C). In contrast to the

5    results obtained with the low enzyme concentration (Figure 3B), the high enzyme concentration promoted opposite strand nicking (e.g., nicking the A-containing strand in a dI/dA duplex oligonucleotide substrate). For I/A and I/G substrates, the nicking primarily occurred at the 3' side one nucleotide beyond the mismatched A or G base. However, opposite strand nicking for I/C and I/T substrates generated an additional

10   product at a lower molecular weight position (Figure 3C). Comparison with length markers suggested that the cleavage site was approximately 2-3 nt at the 5' side of the T or C base as the 38 mer and 27 mer represent cleavage products right after the T or C base at the 3' side (Figure 3D). The opposite strand nicking was incomplete at I/C and I/T, while the deoxyinosine cleavage was complete, indicating that the 5' nicking

15   of C or T had occurred after nicking of the deoxyinosine-containing strand. It is unknown whether the high yield opposite strand nicking at the 5' side in I/C is associated with the fact that I/C forms a Watson-Crick base-pair (Xuan, J. C. et al., Nucleic Acids Res., 20:5457-64 (1992), which is hereby incorporated by reference) and whether the low yield opposite strand nicking at the 5' side in I/A and I/G is

20   associated with the fact that they form non-Watson-Crick base-pairs. Corfield, P. W., et al., Nucleic Acids Res., 15(19):7935-49 (1987), which is hereby incorporated by reference. The opposite strand nicking at the 5' side of the I/C and I/T base-pairs was not observed with C/I or T/I substrates, indicating that either the nicking products were less stable at 65°C incubation and being degraded as single-stranded DNA or

25   the nicking at these substrates were less efficient due to sequence context. These results suggest that nicking events in general occur at the 3' side, but the enzyme is capable of cleaving at the 5' side at the opposite strand complementary of an deoxyinosine-containing strand. An earlier study suggested that *E. coli* endonuclease V cleaves at the 5' side of methylbenz[a]anthracene adducts. Demple, B. et al., J.

30   Biol. Chem., 257(6):2848-55 (1982), which is hereby incorporated by reference. Thus, the enzyme is able to make a 5' incision at some lesion sites. The above results confirmed that the purified enzyme is an endonuclease V.

**Example 5 -** **Effect of Reaction Buffer on *Tma* Endonuclease V Activity and Specificity**

5      Since enzyme activity and specificity can be influenced by the metal cofactor used by an enzyme, *Tma* endoV mismatch cleavage activity in the presence of either $Mg^{2+}$, $Mn^{2+}$, $Fe^{2+}$, $Ca^{2+}$, $Co^{2+}$, $Ni^{2+}$, $Cu^{2+}$, $Zn^{2+}$, $Cd^{2+}$, $Ba^{2+}$ or $Sr^{2+}$ was analyzed. The concentration of each metal was 5 mM. The reaction mixture contained 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM metal chloride,

10     100 nM *Tma* endoV and 10 nM oligonucleotides containing base-mismatch either (A/A), or (C/T), or (C/C), a regular oligonucleotide without base mismatch was used as a control. The mixture was incubated at 65 °C for 30 min and loaded on a gel for electrophoresis. Cleavage products and remaining substrates were quantified using the GeneScan analysis software versions 2.1 or 3.0. Cleavage products were only

15     observed in the presence of $Mg^{2+}$ or $Mn^{2+}$, indicating that these two cations are the only metal cofactors of *Tma* endo V in the set tested. Figure 4 shows *Tma* endo V activity in the presence of different concentrations of $Mg^{2+}$ or $Mn^{2+}$ using double-stranded oligonucleotide DNA with an A/A mismatch as substrate. The mismatch cleavage activity was most active at $Mg^{2+}$ concentrations of 2-7 mM and at $Mn^{2+}$

20     concentrations of 0.4-1.2 mM.

**Example 6 -** **Cleavage of Base Mismatch-Containing Oligonucleotides**

Base mismatch nicking was investigated using 12 substrates containing

25     different base mismatches (Figure 5). The cleavage reactions were performed at 65°C for 30 minute in a 20 µl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM MgCl2 or 1 mM MnCl2, 10 nM DNA substrate and the indicated amount of purified *Tma* endonuclease V protein. The reaction was terminated by adding an equal volume of GeneScan stop solution. The reaction

30     mixtures were then heated at 94°C for 2 min. and cooled on ice. 3 µL of samples were loaded onto a 10% GeneScan denaturing polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an ABI 377 sequencer (Perkin Elmer). Cleavage products and remaining substrates were quantified using the GeneScan analysis software versions 2.1 or 3.0. With $Mg^{2+}$ as the metal cofactor,

the enzyme needed a higher enzyme-to-substrate (E:S) ratio to make an incision at a mismatch (Figure 5A-5B). With $Mn^{2+}$ as the metal cofactor, the nicks at mismatch substrates occurred at lower E:S ratios (Figure 5C-5D). The cleavage reactions of mismatches did not proceed to completion, as even at higher E:S ratios there were still

5   significant remaining mismatch containing substrates while the nonspecific nicking became significant (Figure 5B). The cleavage sites were identical to those identified using deoxyinosine-containing substrates, i.e., at the 3' side one nucleotide after the mismatches. The mismatch nicking was most efficient with an A or G base, and less so with a T base. C base was nicked much less efficiently when it base-pairs with an

10  A or a T base, and cleavage was not observed when it base-pairs with a C. This mismatch cleavage profile is in agreement with the *E. coli* enzyme. Yao, M. et al., J. Biol. Chem., 269(50):31390-96 (1994), which is hereby incorporated by reference. However, no strand-preferred or terminus-dependent mismatch cleavage was observed as previously reported using the *E. coli* enzyme (Yao, M. et al., J. Biol.

15  Chem., 269(50):31390-96 (1994), which is hereby incorporated by reference). Base mismatch cleavage occurred at both top and bottom strands regardless of the distance between the mismatch base and the 5' termini (Figure 2A, Figure 5A). The finding that *Tma* EndoV was capable of cleavage of both top and bottom strands regardless of the distance between the mismatch base and the 5' termini was unanticipated and

20  demonstrates that this enzyme has unique properties which distinguish it from the *E. coli* enzyme. The same authors who characterized the mesophilic *E. coli* EndoV enzyme most recently characterized the thermostable *A. fulgidus* EndoV enzyme (Liu et. al., Mutation Research 461:169-177 (2000). The *A. fulgidus* EndoV enzyme only had activity against inosine containing DNA, not against mismatches or other lesions.

25  Thus, it cannot be presumed that a thermostable EndoV would have activity on substrates containing base mismatches.

Table 1 provides a summary of results with *Tma* endonuclease V cleavage of heteroduplexed synthetic substrates containing single base mismatches. Note that for every possible base change, there are two possible heteroduplexed

30  products which may form: A↔G (A-C, G-T); C↔T (C-A, T-G); A↔C (A-G, C-T); G↔T (G-A, T-C); A↔T (A-A, T-T), and G↔C (G-G, C-C).

**Table 1.  Summary of *Tma* endonuclease V cleavage of heteroduplexed synthetic substrates containing single base mismatches.**

| Base change (Wt↔Mt) | A↔G | C↔T | A↔C | G↔T | A↔T | G↔C |
|---|---|---|---|---|---|---|
| **Heteroduplex I:** UpperStrand (Wt) | A  +++ | C  + | A  ++ | G  ++ | A  +++ | G  +++ |
| BottomStrand(Mt) | C  - | A  ++ | G  +++ | A  ++ | A  +++ | G  +++ |
| **Heteroduplex II:** UpperStrand (Mt) | G  ++ | T  ++ | C  + | T  ++ | T  + | C  - |
| BottomStrand (Wt) | T  ++ | G  +++ | T  ++ | C  - | T  + | C  - |

Note:
UpperStrand:
5'-FAM-TA CCC CAG CGT CTG CGG TGT TGC GTX AGT TGT CAT AGT TTG ATC CTC TAG TCT TGT TGC GGG TTCC-3' (SEQ. ID. No. 5)

BottomStrand:
3'- GGG GTC GCA GAC GCC ACA ACG CAY TCA ACA GTA TCA AAC TAG GAG ATC AGA ACA ACG CCC-TET-5' (SEQ. ID. No. 6)

Cleavage symbols:
(+++): high intensity cleavage. (++): intermediate intensity cleavage. (+): low intensity cleavage. (-) no cleavage

The cleavage of these heteroduplexed products are not always identical (i.e. compare A-C with C-A), and this reflects subtleties in the structure of the DNA as a consequence of neighboring sequence variation.  Nevertheless, for each possible base change, signal is generated for at least one top strand and at least one bottom strand. Thus, the *Tma* EndoV enzyme should be able to recognize any possible single base mutation or polymorphism.

**Example 7 -    Non-Specific Cleavage Activity of *Tma* Endonuclease V on Single Stranded and Double Stranded DNA**

In order to determine the non-specific cleavage activity of *Tma* endoV, the cleavage activities on a single strand oligonucleotide and a regular plasmid were measured.  The single strand DNA cleavage reactions were performed at 65°C for 30 minute in a 20 μl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT,

2% glycerol, in 5 mM MgCl₂ or 0.6 mM MnCl₂, 10 nM single strand DNA substrate, and the indicated amount of purified *Tma* endonuclease V protein.

The plasmid cleavage reactions were performed at 65°C for 30 minute in a 20 µl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2%
5    glycerol, 5 mM MgCl₂ or 1 mM MnCl₂, 10 nM plasmid pFB 7.6, and the indicated amount of purified *Tma* endonuclease V protein.

The reaction was terminated by adding an equal volume of GeneScan stop solution. The reaction mixtures were then heated at 94°C for 2 min. and cooled on ice. Three microliter of samples were loaded onto a 10% GeneScan denaturing
10   polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an ABI 377 sequencer (Perkin Elmer). Cleavage products and remaining substrates quantified using the GeneScan analysis software versions 2.1 or 3.0.

The enzyme nicked the AP site or uracil-containing strand specifically
15   at low enzyme concentrations (Figure 6A, lanes 3-4 and 6-7). When the enzyme concentration was increased to 100 nM (E:S = 10:1), opposite strand nicking started to occur (Figure 6A), lanes 5 and 8), suggesting that opposite strand nicking is not unique to inosine-containing substrates. The enzyme formed a weak but distinct complex with an AP site substrate, but not with a uracil substrate (Figure 6B),
20   suggesting that the enzyme does not solely rely on base recognition for achieving ground state binding. The lack of stable binding to a uracil site is consistent with genetic studies which indicate that endoV does not play a significant role in uracil repair. Guo, G. et al., J. Bacteriol, 180:46-51 (1998), which is hereby incorporated by reference.

25          The binding data obtained from I/I substrate showed that the enzyme may be able to interact with inosine substrate in a single-stranded fashion. Previous studies demonstrate that *E. coli* endoV cleaves single-stranded inosine substrate (Yao, et al., J. Biol. Chem., 271:30672-76 (1996), which is hereby incorporated by reference). To gain a better understanding of how the enzyme cleaves single stranded
30   DNA, cleavage and binding of inosine, AP site, and uracil substrates were examined. *Tma* endoV cleaved single stranded inosine substrate with either Mg²⁺ or Mn²⁺ as the metal cofactor (Figure 6C). The cleavage of single stranded AP site or uracil

- 42 -

appeared to prefer using $Mn^{2+}$ as the metal factor (Figure 6C). In addition, $Mn^{2+}$
promoted the cleavage of non-specific single stranded DNA (Figure 6C). The
nonspecific endonuclease activity was further confirmed using a supercoiled plasmid
substrate (Figure 6D). With $Mg^{2+}$ as the metal cofactor, the non-specific

5    endonuclease activity primarily nicked the plasmid once. With $Mn^{2+}$ as the metal
cofactor, the enzyme could nick a plasmid molecule at least twice to generate a linear
plasmid (Figure 6D). The two nicking events are sequential as evidenced by the
appearance of nicked plasmid intermediate. The conversion of supercoiled plasmid
into nicked or linear plasmid suggests that the enzyme does not need free 5' or 3' ends

10   to access a DNA molecule.

As with the double stranded inosine substrate, binding to single-
stranded inosine substrate also requires a metal cofactor (Figure 6E). The binding ·
affinity to the single-stranded inosine substrate appeared to be weaker than the
double-stranded (Figure 6E). A stable complex was formed in the presence of $Mg^{2+}$,

15   suggesting that *Tma* endoV maintained a relatively high affinity to the nicked single-
stranded product (Figure 6F). Single-stranded inosine cleavage activity may help
repair damage at transient single-stranded regions during replication and transcription.

This indicates that nonspecific cleavage is more prevalent with $Mn^{2+}$
as the metal cofactor. In addition, the conversion of a supercoiled plasmid into nicked

20   and linear forms suggests that the enzyme does not need free 5' or 3' end to access a
DNA molecule. Since the above results demonstrate that *Tma* endoV cleavage is
more specific in the presence of $Mg^{2+}$ than $Mn^{2+}$, $Mg^{2+}$ was determined to be the
preferred metal cofactor in the reaction buffer.

25   **Example 8 -   The Effects of pH on the Base-Mismatch Cleavage Activity of *Tma*
Endonuclease V.**

pH can exert a profound effect on mismatch cleavage. The substrates
in this assay are a group of four oligonucleotides, three of them contain mismatches

30   (A/A), (C/T), and (C/C) respectively, the other is a regular oligonucleotide without
mismatch. The cleavage reactions performed at 65°C for 1 hour in the buffer
containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM $MgCl_2$ (or 1

mM $MnCl_2$), 10 nM DNA substrate, indicated that the amount of purified *Tma* endonuclease V protein with different E:S ratios.

The following buffers were used in making different pH: 20 mM MES (pH 6.0), 20 mM MOPS (pH 6.5), 10 mM HEPES (pH 7.0-7.5), 20 mM Tris (pH 8.0-8.5). **A.** Reactions performed with 100 nM endonuclease V (E:S = 10:1) in the presence of 5 mM $MgCl_2$. **B.** Reactions performed with 10 nM endonuclease V (E:S = 1:1) in the presence of 1 mM $MnCl_2$.

The reaction mixtures were then heated at 94 °C for 2 min. and cooled on ice. Three microliter samples were loaded onto a 10% GeneScan denaturing polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an ABI 377 sequencer (Perkin Elmer). Cleavage products and remaining substrates were quantified using the GeneScan analysis software versions 2.1 or 3.0.

Figure 7 shows that the pH of the reaction buffer can exert profound effects on mismatch cleavage. Nicks at the mismatch position became observable at pH 6.5 and reached a maximum at pH 7.5 with concurrent increases in nonspecific cleavage both in the presence of either 5 mM $Mg^{2+}$ (E:S=10:1), Figure 7A, or 1 mM $Mn^{2+}$ (E:S=1:1) Figure 7B. Consistent with previous studies for *E. coli* endonuclease V, (Gates, F. T., 3rd and Linn, S., J. Biol. Chem., 252(5):1647-53 (1977), which is hereby incorporated by reference) and *E. coli* DNA polymerase (Eckert, K. A., et al., "Effect of Reaction pH on the Fidelity and Processivity of Exonuclease-Deficient Klenow Polymerase" J. Biol. Chem., 268(18):13462-71 (1993), which is hereby incorporated by reference). *Tma* endonuclease V thus became more nonspecific at high pH conditions.

**Example 9 -   The Effects of Salt on the Cleavage of Oligonucleotides Containing a Base Mismatch**

To study how reaction conditions may affect base mismatch cleavage, representative mismatch cleavage was tested at different NaCl concentrations. The substrates in this assay were a group of four oligonucleotides, three of them containing (A/A), (C/T), and (C/C) mismatches, respectively, while the other was a regular oligonucleotide without mismatch. The cleavage reactions were performed at

65°C for 30 minute in a 20 μl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM $MgCl_2$ or 1 mM $MnCl_2$, 10 nM DNA substrate, and the indicated amount of purified *Tma* endonuclease V protein. The concentration of NaCl ranged from 0-250 mM with 50 mM intervals. The reaction was terminated by

5     adding an equal volume of GeneScan stop solution. The reaction mixtures were then heated at 94 °C for 2 min. and cooled on ice. 3 μL of samples were loaded onto a 10% GeneScan denaturing polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an ABI 377 Sequencer (Perkin Elmer). Cleavage products and remaining substrates were quantified using the GeneScan

10    analysis software versions 2.1 or 3.0.

It was apparent that the enzyme preferred a low salt environment for mismatch cleavage with either $Mg^{2+}$ or $Mn^{2+}$. With $Mg^{2+}$ as the metal cofactor, the mismatch cleavage yields were highest without salt. With $Mn^{2+}$ as the metal cofactor, the mismatch cleavage yields were highest with 50 mM NaCl. See Figure 8. This is

15    in agreement with the notion that increased salt concentrations reduce DNA binding affinity. No cleavage was observed with either the C-C mismatch or A-T match under these conditions.

From the above experiments, an optimal reaction buffer condition in which *Tma* endo V mismatch cleavage is maximized and nonspecific mismatch

20    cleavage is minimized was determined. The optimal conditions are 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, and 5 mM $MgCl_2$. These conditions were determined from data primarily using oligonucleotides as substrate. Therefore, the optimal condition may vary when different substrates, such as genomic DNA, are utilized. In addition, this optimal condition is one that appears best with respect to

25    cleavage characteristics most desirable in the context of the present invention, but it should be noted that sub-optimal conditions are also compatible in the context of the invention.

### Example 10 - Optimization of $Mg^{2+}$ and $Mn^{2+}$ Concentration in *Tma* Endonuclease V Cleavage Reaction Condition When Synthetic Oligonucleotide DNA was used as Substrate

5      Using fluorescences labeled double strand oligonucleotide containing (A/A) mismatch as the substrate, the cleavage activity of *Tma* endoV was measured in different concentrations of $Mg^{2+}$ or $Mn^{2+}$. The cleavage reactions were performed at 65°C for 30 minute in a 20 μl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, unless otherwise specified, 10 nM DNA substrate, different

10    concentrations of $Mg^{2+}$ or $Mn^{2+}$, and 100 nM *Tma* endoV (in the presence of $Mg^{2+}$) or 10 nM *Tma* endoV (in the presence of $Mn^{2+}$).

       The reaction was terminated by adding an equal volume of GeneScan stop solution ( 50 mM EDTA, 80% formamide, 1% blue dextran). The reaction mixtures were then heated at 94°C for 2 min. and cooled on ice. 3 μL of samples

15    were loaded onto a 10% GeneScan denaturing polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr in an ABI 377 sequencer (Perkin Elmer). Cleavage products and remaining substrates were quantified using the GeneScan analysis software versions 2.1 or 3.0 (Perkin Elmer). The quantitative results are shown in Figure 4. The optimal concentration for $Mg^{2+}$ is 2-7 mM and for

20    $Mn^{2+}$ is 0.4-1.2 mM in the cleavage of DNA substrate containing a base mismatch.

### Example 11 - PCR Amplification

       Genomic DNA containing mutations in *k-ras* gene codon 12 and 13

25    were extracted from cell lines containing the mutations. Cell line ht 29 or sw1417 contains normal genomic DNA. Cell line sw620 or sw480 has DNA containing pure g12v(g→t) mutation. The ratio of wild type-to-mutant g12d(g→a) in the genomic DNA extracted from cell line ls180 is 1:1.8. The ratio of wild type-to-mutant g12a(g→c) in the DNA extracted from cell line sw1116 is 1:0.7. The ratio of wild

30    type-to-mutant g13d(g→a) in the genomic DNA extracted from cell line hct 15 or dld 1 is 1:1.1.

       In carrying out the PCR amplification process, forward and reverse PCR primers can be synthesized with 5' end labels of TET and 6-FAM (PE-Biosystems, Foster City, CA). These two fluorescent groups appear green and blue,

respectively, when analyzed by an ABI 377 DNA sequencer. Differential labeling of the top and bottom strands allows one to distinguish cleavage products from each strand independently. To minimize non-specific cleavage of TET and 6-FAM labels by *Tma* endoV, three additional cytosine deoxynuclotides were synthesized on the 5'

5      end of each primer. Examples of suitable primers are shown in Table 1A.

**Table 2A:  PCR Primer Sequences for Amplifying Cancer Gene Fragments.**

In the process of purification of PCR primers, 200 ng of labeled
5   primers was dissolved in 20 µl of ddH$_2$O and was mixed with an equal volume of
formamide.  After incubation at about 64°C for 2 min, the primers were loaded on a
10% polyacrylamide gel containing 7 M urea.  After electrophoresis, the gel slices

containing pure primers were cut out and soaked in TNE solution (0.1 M Tris-HCl (pH 8.0), 0.5 M NaCl, 5 mM EDTA) at 37°C overnight. The solution containing gel slices was removed and loaded on a Sep-Pak Cartridge C-18 (Waters, Milford, Massachusetts) pre-washed with methanol and water. After washing with 20 ml of

5     ddH$_2$O, the primers were eluted out with 2 ml of elution buffer (5 mM TEAA (triethylamine acetate), 50% methanol) and dried with a speed vacuum. The pellets were suspended with TE buffer. PCR reactions were performed in a GeneAmp PCR System 2400 or GeneAmp PCR System 9700. 50 μl of PCR reaction solution contains 10 mM Tris-HCl (pH 8.3), 50 mM KCl, 200 μM of each dNTP, 0.2 μM of

10    primers, 2.5 mM MgCl$_2$, and about 100 ng genomic DNA or amplicons. In the amplification of *VHL* exon 1 with high GC content, 2% DMSO was included in the PCR reaction mixture..

PCR amplification may be directly from genomic DNA or, alternatively, from amplicon(s) containing the fragment(s) of interest.

15    Thermocycling conditions for the PCR reaction should be adjusted to reduce the amplification of non-specific fragments. Table 2B shows typical thermocycling conditions for various genes.

**Table 2B: PCR Cycling Conditions for Amplifying Fragments in Different Genes.**

| Gene | Exon | DNA polymerase | Initial denature | Cycle reaction cycle number | Cycle reaction reaction | Final extension |
|------|------|----------------|------------------|-----------------------------|-------------------------|-----------------|
| *K-ras* | Exon 1 | AmpliTaq | 94 °C for 2 min | 30 | 94 °C for 15 sec, 60 °C for 2 min | 72 °C for 7 min |

Note: for Amplitaq and Taqplus DNA polymerase, after initial denature step, DNA polymerase was added to perform hot start PCR. For gold Taq DNA polymerase, DNA polymerase was included in the reaction mixture before PCR reaction starts. The PCR machine is GeneAmp PCR system 2400 or 9700 (Perkin Elmer).

**Example 12 - Preparation Of Heteroduplex DNA Substrates**

PCR fragments were incubated with proteinase K (20 mg/ml, QIAGEN) in a ratio of 1 µl of proteinase K to 12 µl of PCR products to remove *Taq* DNA polymerase. The reaction was carried out at 70°C for 10 min and at 80°C for 10

min to inactivate the Proteinase K. The mixture was heated at 94°C for 1 min, 65°C for 15 min and then cooled down to room temperature to form heteroduplex DNA. For genomic DNA from cell lines containing more mutant than normal DNA, such as cell line LS 180, PCR fragments from normal genomic DNA were added to make the

5     final ratio (mutant -to-wild type) 1:1. The ratio of mutant to wild type in cell line SW1116 is 0.7:1.0, and the pure mutant DNA is not available, so the genomic DNA alone was treated as described in the following text. If the genomic DNA is purified from blood, for example, where the target DNA is a mutation in the *APC, BRCA 1, BRCA 2* and *VHL* genes, the PCR fragments were treated as described before without

10    adding wild-type PCR fragments.

### Example 13 - Optimization of Conditions of Mutation Detection by *Tma* endoV/ Ligase when Using Heteroduplex PCR Fragments as Substrate.

15    When synthetic double stranded oligonucleotides (60-66 mer) were used as the DNA substrate for endoV cleavage, the optimal buffer condition is 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM $MgCl_2$ in which *Tma* endoV has high specific cleavage activity and low non-specific cleavage activity. However, when an approximately 300 bp PCR fragment containing the G12V mutation in *k-ras*

20    gene was used as the substrate, cleavage was not observed. For this *Tma* endo V cleavage assay, a variety of heteroduplex PCR fragments containing K-*ras* codon 12 mutation were used as substrates. In these experiments, a mixture of wild-type and G12V mutant DNA PCR amplified fragments were used. The two resultant heteroduplexed fragments contain G-A and T-C mismatches, respectively. Cleavage

25    of both top and bottom strand were observed, products were separated on an ABI 377 DNA sequencing apparatus, and amount of cleavage product was quantified using GeneScan 3.0 analysis software (PE-Biosystems, Foster City, CA). Figure 9 demonstrates that adding 5% DMSO to the reaction will enhance mismatch cleavage activity approximately 2-3 fold. Other organic solvents which may enhance mismatch

30    cleavage include dimethyl formamide, ethylene glycol, glycerol, formamide, etc.

A second approach to improving cleavage involved the addition of betaine, N,N,N-trimethylglycine. Betaine was initially used to equalize the melting temperatures of DNA fragments having different GC content. It was found that in

certain "isostabilizing" concentrations of betaine, AT and GC pairs are equally stable. Rees, W. A., et al., Biochemistry, 32:137-44 (1993), which is hereby incorporated by reference. Betaine was also used as an additive to facilitate PCR amplification of regions with high GC content. Henke, W. et al., "Betaine Improves the PCR

5    Amplification of GC-Rich DNA Sequences," Nucleic Acids Res., 25:3957-58 (1997), which is hereby incorporated by reference.

Figure 10 shows that the addition of betaine to the reaction buffer can facilitate the base mismatch cleavage activity of *Tma*. Endo V, but it does so in a fragment dependent fashion. For PCR fragments with a low GC content, such as ones

10   generated from the *APC* gene, the cleavage activity reached a maximum of 2 fold stimulation at 1.0 M betaine. For PCR fragments with a high GC content, for example the K-*ras* fragments, maximum cleavage activity was observed at 1.5 M betaine and resulted in a greater stimulation of 2.7 fold. The relative stimulation for both high and low GC content fragments was approximately the same, 2 fold, at 1 M

15   betaine.

The effect of NaCl was also re-examined for heteroduplex fragments, and Figure 11A demonstrates that addition of NaCl inhibits the cleavage reaction. At 50 mM NaCl, the cleavage reaction is almost completely inhibited. Figure 11B shows the effect of KCl on the mismatch cleavage activity of *Tma* endoV. For this assay

20   100 ng of heteroduplex PCR fragments containing the K-*ras* G12V (G→T) mutation was used as substrate, and the reaction was carried out at 65 °C for 1 hour in a modified optimal reaction buffer (2.0 M betaine, 10% DMSO) with 100 nM *Tma* endonuclease V and varying concentrations of KCl. The results show that the effect of KCl is indeed similar to that of NaCl, and that in the presence of 50 mM KCl, *Tma*

25   endoV cleavage activity is almost completely inhibited. Therefore, in the ligation step of this invention, the *Tma* endoV cleavage activity is essentially eliminated. These results confirm that no additional salt should be included in the reaction buffer.

The above analysis suggests that when PCR fragments are used as substrates, the addition of 5% DMSO and 1 – 1.5 M betaine to the reaction can

30   significantly enhance specific cleavage activity of *Tma* endo V, while the addition of salt should be avoided.

Using the new optimal reaction conditions, a time course of the *Tma* endo V cleavage reaction was performed at 65 °C using PCR fragments containing the K-*ras* G12D(G→A) mutation (Figure 12). In these experiments, a mixture of wild-type and G12D mutant DNA PCR amplified fragments were used. The two

5    resultant heteroduplexed fragments contain G-T and A-C mismatches, respectively. Cleavage of both top and bottom strand were observed, products were separated on an ABI 377 DNA sequencing apparatus, and the amount of cleavage product was quantified using GeneScan 3.0 analysis software. The products increased linearly over the hour time course. Longer incubations can lead to an undesirable increase of

10    nonspecific products. Therefore, the optimal reaction conditions for *Tma* endoV using heteroduplex PCR fragments as the substrate, in a reaction buffer containing 10 mM HEPES (pH 7.4), 5 mM $MgCl_2$, 1 mM DTT, 2% glycerol, approx. 1-1.5 M betaine, and 5 % DMSO, and an incubation at 65 °C for 1 h.

Figure 13 (- DNA Ligase Lanes) demonstrates that the new optimal

15    reaction conditions result in high activity and relatively good specificity of the *Tma* endo V enzyme when PCR fragments are used as substrates. Nevertheless, non-specifc nicking is still observed, and as a result there exists significant background signal.

20    **Example 14 - Ligation Reaction Condition with $NAD^+$ DNA Ligase**

The optimal reaction buffer for Tsp.AK16D ligase is 20 mM Tris-HCl pH 8.5, 5 mM $MgCl_2$, 50 mM KCl, 10 mM DTT, 1 mM $NAD^+$, 20 µg/ml BSA. Tong, J., et al., "Biochemical Properties of a High Fidelity DNA Ligase from *Thermus* Species

25    AK16D," Nucleic Acids Res., 27:788-94 (1999), which is hereby incorporated by reference. Fifteen µL of the reaction mixture from the EndoV cleavage were added to 2 µl of 10 x supplemental buffer (200 mM Tris-HCl, pH 8.5, 12.5 mM $MgCl_2$, 500 mM KCl, 100 mM DTT and 200 µg/ml BSA), 1 µl of 20 mM $NAD^+$, and 2 µl of 10-60 nM *Tsp*. AK16D DNA ligase. The final concentration of the mixture is: 20 mM Tris-HCl

30    pH 8.5, 5 mM $MgCl_2$, 50 mM KCl, 10 mM DTT, 1 mM $NAD^+$, 20 µg/ml BSA and 1-6 nM AK16D DNA ligase. The mixture was incubated at 65 °C for 20 min and terminated by adding an equal volume of GeneScan stop solution (50 mM EDTA, 1% blue dextran and 80% formamide). The reaction mixtures were then heated at 94°C for 2 min. and

cooled on ice. 2-3 μl of the mixture were loaded onto a 6% denaturing polyacrylamide gel and electrophoresed for 1 hr in an ABI 377 sequencer (Perkin Elmer) under the following conditions: voltage of 1000 volts, current of 60 mA, power of 200 w, and gel temperature of 45 °C. 6-FAM and TET were the fluorescent group labelled in top and
5   bottom strand primers, respectively. They appear blue and green, respectively, with an ABI DNA sequencer 377. Therefore, it can be concluded that the TET labeled (green) cleavage bands were generated from the top strand and FAM labeled (blue) cleavage bands were from the bottom strand. Since TAMRA labeled GeneScan Molecular size standard 500 (red bands) was loaded on the same gel, the molecular weight of cleavage
10   products could be estimated by comparison of the mobility of the size standards to the cleavage products using the GeneScan analysis software versions 2.1 or 3.0a.

**Example 15 - Detection of Codon 12 and 13 Mutations in K-ras Gene.**

15          The strategy of mutation scanning with *Tma* endoV/AK16D DNA ligase was first tested in the detection of codon 12 and 13 mutations in the K-*ras* gene. Genomic DNA from cell lines containing mutations in codon 12 and 13 were used as templates for PCR amplification. The cell lines containing K-*ras* mutation are listed in Table 3 as follows:

20

**Table 3**

| Cell Line | Genotype | Ratio of mutant-to-wild type |
|-----------|----------|------------------------------|
| HT29 SW1417 | Wild type | |
| SW1116 | G12A (G→C) | 0.7:1 |
| DLD 1 HCT 15 | G13D (G→A) | 1:1 |
| LS180 | G12D (G→A) | 1.8:1 |
| SW620 Sw480 | Pure G12V (G→T) | |

The sequence of top strand PCR primer was:
25   Tet- 5' -CCCCATAGTGTATTAACCTTATGTGTGACATGTTC-3' (SEQ. ID. No. 33),
and for the bottom strand primer was
Fam 5'- CCCCAAAATGGTCAGAGAAACCTTTATCTGTATC-3' (SEQ. ID. No. 34).

The PCR reaction was performed at 94 °C for 2 min, followed by the addition of AmpliTaq DNA polymerase, and, then, 30 cycles of 94 °C for 15 sec, 60 °C for 2 min. A final extension was then performed at 72 °C for 7 min. A wild-type PCR fragment from genomic DNA was then mixed with the mutant PCR fragment in
5    a ratio of 1:1. In order to remove *Taq* DNA polymerase, 1 μl of proteinase K was added (20 mg/ml, QIAGEN) for every 12 μl of PCR products. This reaction was incubated at 70 °C for 10 min and at 80 °C for 10 min to inactivate the Proteinase K. Heteroduplex fragments were then formed by heating the mixture at 94 °C for 1 min, 65 °C for 15 min, and then cooling down to room temperature. The PCR fragments
10   generated from the genomic DNA of cell line SW1116 did not require the addition of wild type PCR fragements.

For the cleavage reaction, the standard reaction mixture consisted of 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM $MgCl_2$, 5% DMSO, 1.5 M betaine, 100 ng PCR products, 500 nM, and purified *Tma* endonuclease V protein.
15   The reaction mixture was incubated at 65°C for 1 hour and was terminated by adding 15 μl of reaction mixture to 2 μL of 10x ligase supplemental buffer (200 mM Tris-HCl, pH 8.5, 12.5 mM $MgCl_2$, 500 mM KCl, 100 mM DTT, and 200 μg/ml BSA). The KCl of the 10x ligase supplemental buffer is responsible for the inhibition of *Tma* endoV cleavage activity. Next, 1 μl of 20 mM $NAD^+$, and 2 μl of 60 nM AK16D
20   DNA ligase was added to bring the final concentration of the ligase reaction mixture to 20 mM Tris-HCl pH 7.6, 5 mM $MgCl_2$, 50 mM KCl, 10 mM DTT, 1 mM $NAD^+$, 20 μg/ml BSA, and 6 nM AK16D DNA ligase. The mixture was incubated at 65 °C for 20 min and terminated by adding an equal volume of GeneScan stop solution (50 mM EDTA, 1% blue dextran, and 80% formamide). The reaction mixture was then
25   heated at 94°C for 2 min. and cooled on ice. 3 μl of the mixture were loaded onto a 6% denaturing polyacrylamide gel and electrophoresed for 1 hr on an ABI 377 sequencer (Perkin Elmer) at 1000 volts, 60 mA, 200 W, and a gel temperature of 45°C.

After endoV cleavage, none of the major cleavage bands were found in
30   the pure wild type and pure mutant G12V. Two major cleavage bands were found in the sample of G12+G12V and G12+G12D (LS180). The length of the FAM labeled (blue band; top strand cleavage product) is about 157-160 bp which is in the range of

the expected length of 159 bp for a mismatch cleavage . The length of TET labeled (green band; bottom strand cleavage product) is around 118 bp which is also close to the expected value of 116 bp for a mismatch cleavage. In addition to the G12V mutation, mutations G12D and G12A were also detected in similar assays. In the

5    G12D assay, both top and bottom strand cleavage products were observed, and their intensities were only a little less than that of G12V. In the detection of G12A, the cleavage of both strands was again observed. The intensity of the top strand product was almost the same as that of G12D, but the intensity of the bottom strand product was much lower than those of the other two mutants. The mutation G13D was not

10   detected.

Figure 13 demonstrates how the addition of the ligation step dramatically decreases background due to non specific nicking. For this assay, PCR fragments were generated from DNA samples that were homozygous for either the wt or mutation at position G12 in *kras*, or heterozygous at this position. Without the ligation step,

15   nonspecific cleavage is observed in all the samples. But with the addition of the Tsp. AK16D ligase step, this background signal is dramatically reduced. Only in heterozygous samples (i.e. the last two lanes of each set) does one observe cleavage associated with a heteroduplex mismatch, and these results demonstrate that the additional ligation step does not compromise specific mismatch cleavage. Therefore, the

20   additional ligation step is able to reduce background due to cleavage at non-mismatch positions but does not ligate cleavages at mismatch cleavage sites.

In addition to the major mismatch cleavage products, some non-specific cleavage bands were also observed. There is one non-specific band in all samples which migrates above the blue (i.e. top strand) cleavage products present .

25   There are also two non-specific cleavage products, one is blue and the other is green, which migrate with low molecular weight products and are present in all four samples. After incubation with 1-6 nM DNA ligase, the non-specific band above the blue cleavage band decreases in intensity, indicating the non-specific nick was sealed by the DNA ligase. The low molecular weight non-specific bands are still present

30   even when the concentration of AK16D ligase was raised to 6 nM (See Figure 13). This suggests that these may be non-ligatable degradation products or, alternatively,

short fragments which have denatured from the substrate during the 1 hour Endo V incubation at 65°C in organic solvents.

In order to characterize the sensitivity of this invention, base-mismatches in PCR fragments containing *K-ras* exon 1 mutations were assayed under

5    varying ratios of mutant-to-wild type DNA. With this invention the efficiency of cleavage for a 1:1 mutant-to-wild type DNA ratio for DNA containing *K-ras* mutations, G12V, G12D and G12A is typically high, medium, and low, respectively. Utilizing this set of mutations allows one to screen for sensitivity over a wide range of cleavage efficiencies and should more accurately reflect the useful range of this

10    invention. PCR fragments containing K-*ras* exon1 mutations, G12V, G12D, and G12A were separately mixed with wild type PCR fragments in mutant-to-wild type ratios of 1:1, 1:2, 1:5, 1:10, 1:20, 1:50, and 1:100. These fragment mixtures were then assayed using the above mentioned *Tma* EndoV and DNA ligase conditions.

Figure 14 shows the amount of cleavage products for the different ratio of mutant-to-

15    wild type DNA. The results indicate that cleavage signals can be distinguished from background for mutant-to-wild type ratios of up to 1:20 for all three mutantions. For ratios greater than 1:20, the signal at the correct position was still observed; however, it is difficult to conclusively distinguish between cleavage products and background. From this assay, it appears that the limit of sensitivity for the present invention is

20    approximately 1:20 (mutant-to-wild type ratio).

**Example 16    Detection of Various Point Mutations in *p53* and *VHL* Genes.**

To study the versatility of endoV to scan different point mutations, the

25    technique of the present invention was applied to genomic DNA with various point mutations in *p53* and *VHL* genes. Eleven samples containing point mutations in exon 5, 6, 7, and 8 in *p53* and 13 samples containing point mutations in *VHL* were obtained. The sequence of PCR primers for amplifying exons in *p53* and *VHL* genes are listed in Table 2A. PCR thermocycle conditions are listed in Table 2B. From the

30    gel image of the 500 bp VHL exon 1 fragment, a smear was observed, extending from about 180 to 500 bp. This makes it very hard to observe the cleavage products in this region due to the very high GC content in the middle of exon 1 of *VHL*. As a result, interactions between PCR fragments and other regions of the genomic DNA may

occur. If so, the template should be diluted in the second round of PCR amplification to reduce the smear. Therefore, for the second round of PCR amplification, only 1 µL of a 100 fold dilution of the PCR products was used and amplified under the same cycling conditions as discussed previously, but this time for only 15 rounds. The

5    smear was dramatically reduced, and the products were then visible.

Genomic DNA containing *p53* mutations was extracted from tumor samples and PCR amplified. Subsequently, wild-type PCR fragments were added so that equal amounts of mutant and wild type PCR fragments were present. Genomic DNA containing the *VHL* gene mutation was from heterozygous samples, so wild

10   type PCR fragments were not added. In order to remove *Taq* DNA polymerase, 1 µl of proteinase K was added (20 mg/ml, QIAGEN) for every 12 µl of PCR products. This reaction was incubated at 70 °C for 10 min and at 80 °C for 10 min to inactivate the Proteinase K. Heteroduplexed fragments were then formed by heating the mixture at 94 °C for 1 min, 65 °C for 15 min, and then cooling down to room temperature.

15   For the cleavage reaction, the standard reaction mixture consisted of 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM $MgCl_2$, 5% DMSO, 1.5 M betaine, 100 ng PCR products, 500 nM, and purified *Tma* endonuclease V protein. The reaction mixture was incubated at 65°C for 1 hour and was terminated by adding 15 µl of reaction mixture to 2 µL of 10x ligase supplemental buffer (200 mM Tris-

20   HCl, pH 8.5, 12.5 mM $MgCl_2$, 500 mM KCl, 100 mM DTT and 200 µg/ml BSA). Next, 1 µl of 20 mM $NAD^+$ and 2 µl of 60 nM AK16D DNA ligase were added to bring the final concentration of the ligase reaction mixture to 20 mM Tris-HCl pH 7.6, 5 mM $MgCl_2$, 50 mM KCl, 10 mM DTT, 1 mM $NAD^+$, 20 µg/ml BSA, and 6 nM AK16D DNA ligase. The mixture was incubated at 65 °C for 20 min and terminated

25   by adding an equal volume of GeneScan stop solution (50 mM EDTA, 1% blue dextran, and 80% formamide). The reaction mixture was then heated at 94°C for 2 min. and cooled on ice. Three µl of the mixture were loaded onto a 6% denaturing polyacrylamide gel and electrophoresed for 1 hr on an ABI 377 sequencer (Perkin Elmer) at 1000 volts, 60 mA, 200 W, and a gel temperature of 45°C.

30   A summary of the mutation scanning results by this method are provided in Table 4.

**Table 4.** Summary of *Tma* EndoV / Ligase mutation scanning on cancer genes.

| Gene | Exon | Mutation | Surrounding sequences | Change | Cleavage | |

*: (+++): high intensity cleavage. (++); intermediate intensity cleavage. (+) : low intensity cleavage (-) : no cleavage observed.

5

For the *p53* gene, 9 out of the 11 mutations were detected. For the *VHL* gene, 12 out of 13 point mutations were detected. For all of the point mutations not detected, DNA sequencing was performed to PCR fragments of these samples in order to verify the presence of the mutation and the ratio of mutant to wild type DNA.

5 The results showed that the mutations were present in these samples and the ratio of mutant to wild type DNA was approximately 1:1 in all of the samples, except for sample R175H. After adding wild-type PCR fragments to the mutant PCR fragments containing R175H, cleavage assays were repeated, but the results for R175H were still negative.

10 All but four mutations listed in Table 4 could be recognized by *Tma* endonuclease V. The four non-detectable mutations are *K-ras* G13D(G→A), *p53* R175H(G→A), R273C(C→T), and *VHL* G164D(G→A) (Table 4), and the surrounding sequence of each mutation for both top and bottom strand are listed in Table 5.

15

**Table 5. List of Mutations and surrounding sequences for top and bottom strand, with cleavage intensity.**

| Gene | Exon | Mutation | Surrounding Sequences (Wt) | Surrounding Sequences (Mt) | Changes | Mismatches | |

Previous assays with double-stranded oligonucleotide substrates demonstrated that every point mutations can be detected with this method (Figures 3 and 5, Table 4), with mismatches containing cytosine to be the least efficiently cleaved. Even though all four of these mutations generate heteroduplex PCR fragments with cytosine mismatches, so do the vast majority of the mutations surveyed. Therefore, the presence of a cytosine mismatch is not sufficient to explain why these four mutations were not detected. Instead, the data suggests that flanking sequences need to be taken into account. Analysis of the surrounding sequences of the four mutations which could not be cleaved by *Tma* EndoV gives the following consensus sequences: gRcg, rcRc, cgYc, and gYgy. The position of the mutation or polymorphism is underlined and shown in upper case, the last two sequences listed are the complements of the first two sequences (where R and Y stand for a purine and pyrimidine base, respectively). In a very preliminary analysis, the 1st 100 random

single nucleotide polymorphisms (SNPs) from human chromosome 22 were searched for the four refractory sequences, and only one, rcRc, was found (Table 6).

**Table 6. The frequency of *Tma* EndoV refractory sequences in Human Chromosome 22, 1$^{st}$ 100 random SNPs.**

Subsequent computer searches of some 4,000 SNPs in the SNP database revealed the frequency of the gRcg (and complement cgYc) was about 0.1% and the rcRc (and complement gYgy) was about 2%. This preliminary result suggests that the frequency of the four refractory sequences is very low (2%), and it is possible that *Tma* endoV can cleave approximately 98% of the poymorphisms and mutations found in the human genome.

In addition to detecting single base mutations, the analysis demonstrates that the present invention is also capable of detecting small insertions

and deletions (See Table 4). A three base insertion in the *VHL* gene and a two base deletion in *BRCA 1* both resulted in very strong cleavage signals for both strands. A single base deletion in the *VHL* gene also resulted in a strong signal for both strands. The worst results were obtained with a single insertion and a single base deletion in

5    the *BRCA 1* gene. Both for the insertion and deletion only one strand was observed to be cleaved, and the signal was relatively weak for both cases. Despite this lower efficiency, this type of signal is capable of confirming a variation in an unknown sample. These results demonstrate that the present invention can detect small insertions and deletions, and, similar to mutation detection, the efficiency is sequence

10   dependent.

**Example 17**    **Detection of T→A Mutation in Codon 1307 of Exon 15 in the *APC* Gene**

15

The method of the present invention was applied to clinical samples by scanning T→A mutation in codon 1307 in exon 15 of *APC* gene. Nine genomic samples from colon cancer tissues and four wild type samples were assayed.

20   The sequence of the top strand PCR primer was
Tet-5'-CCCCGCTGCCACTTGCAAAGTTTCTTC-3' (SEQ. ID. No. 35)
while the sequence of the bottom strand PCR primers was
Fan-5'- CCCCACTCTGAACGGAGCTGGCAAT-3' (SEQ. ID. No. 36)

25

The PCR reaction condition was listed in Table 2B. Since genomic DNA containing APC mutations were heterozygous, it is not necessary to add wild-type PCR fragments. In order to remove *Taq* DNA polymerase, 1 μl of proteinase K was added (20 mg/ml, QIAGEN) for every 12 μl of PCR products. This reaction was

30   incubated at 70 °C for 10 min and at 80 °C for 10 min to inactivate the Proteinase K. Heteroduplex fragments were then formed by heating the mixture at 94 °C for 1 min, 65 °C for 15 min, and then cooling down to room temperature. The PCR fragments from genomic DNA of cell line SW1116 were directly heated and cooled down to produce heteroduplexes without adding wild type PCR fragments.

For the cleavage reaction, the standard reaction mixture consisted of 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM MgCl$_2$, 5% DMSO, 1.0 M betaine, 100 ng PCR products, 500 nM, and purified *Tma* endonuclease V protein. The reaction mixture was incubated at 65°C for 1 hour and was terminated by adding

5    15 μl of reaction mixture to 2 μL of 10x ligase supplemental buffer (200 mM Tris-HCl, pH 8.5, 12.5 mM MgCl$_2$, 500 mM KCl, 100 mM DTT, and 200 μg/ml BSA). Next, 1 μl of 20 mM NAD$^+$ and 2 μl of 60 nM AK16D DNA ligase was added to bring the final concentration of the ligase reaction mixture to 20 mM Tris-HCl pH 7.6, 5 mM MgCl$_2$, 50 mM KCl, 10 mM DTT, 1 mM NAD$^+$, 20 μg/ml BSA, and 6 nM

10    AK16D DNA ligase. The mixture was incubated at 65 °C for 20 min and terminated by adding an equal volume of GeneScan stop solution (50 mM EDTA, 1% blue dextran, and 80% formamide). The reaction mixture was then heated at 94°C for 2 min. and cooled on ice. Three μl of the mixture were loaded onto a 6% denaturing polyacrylamide gel and electrophoresed for 1 hr on an ABI 377 sequencer (Perkin

15    Elmer) at 1000 volts, 60 mA, 200 W, and a gel temperature of 45°C. The correct mutations was detected in all of the samples no false positives were detected in the wild-type or tumor samples. The cleavage activity was higher in the presence of 1.0 M betaine than that in 1.5 M betaine (Figure 10B), presumably due to the AT rich nature of exon 15 of the *APC* gene. Therefore, the amount of betaine may need to be

20    adjusted, and the GC- content of the region amplified may act as a guide.

**Example 18 - Detection of *k-ras* Mutations in the Diluted Samples**

In order to determine the sensitivity of this invention, PCR fragments

25    containing *K-ras* exon 1 mutations, G12V, G12D, and G12A were used as templates, and the mutation detection abilities of the present invention were assayed in different ratios of mutant-to-wild type DNA ranging from 1:1 to 1:100. The initial ratio in the G12A assay was 0.7:1, because the mutant-to-wild type ratio in the genomic DNA containing the G12A mutation was 0.7:1 and the pure mutant G12A was not

30    available. The sequences of PCR primers are listed in Table 2A, and the PCR thermocycle conditions are listed in Table 2B. In order to remove *Taq* DNA polymerase, 1 μl of proteinase K was added (20 mg/ml, QIAGEN) for every 12 μl of PCR products. This reaction was incubated at 70 °C for 10 min and at 80 °C for 10

min to inactivate the Proteinase K. Heteroduplex fragments were then formed by heating the mixture at 94 °C for 1 min, 65 °C for 15 min, and then cooling down to room temperature.

The PCR fragments containing *K-ras* exon1 mutations, G12V, G12D,

5 and G12A were individually mixed with wild type PCR fragments in the ratio of mutant-to-wild type of 1:1, 1:2, 1:5, 1:10, 1:20, 1:50, and 1:100. For this assay, the total amount of PCR fragments was held constant. Therefore, 100 ng of heteroduplex PCR fragments with different mutant-to-wild type ratios were cleaved with *Tma* endoV and ligated with Tsp. AK16D DNA ligase.

10 For the cleavage reaction, the standard reaction mixture consisted of 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM $MgCl_2$, 5% DMSO, 1.5 M betaine, 100 ng PCR products, 500 nM, and purified *Tma* endonuclease V protein. The reaction mixture was incubated at 65°C for 1 hour and was terminated by adding 15 µl of reaction mixture to 2 µL of 10x ligase supplemental buffer (200 mM Tris-HCl, pH 8.5,

15 12.5 mM $MgCl_2$, 500 mM KCl, 100 mM DTT, and 200 µg/ml BSA). Next, 20 mM $NAD^+$ and 2 µl of 60 nM AK16D DNA ligase were added to bring the final concentration of the ligase reaction mixture to 20 mM Tris-HCl pH 7.6, 5 mM $MgCl_2$, 50 mM KCl, 10 mM DTT, 1 mM $NAD^+$, 20 µg/ml BSA, and 6 nM AK16D DNA ligase. The mixture was incubated at 65 °C for 20 min and terminated by adding an equal

20 volume of GeneScan stop solution (50 mM EDTA, 1% blue dextran, and 80% formamide). The reaction mixture was then heated at 94°C for 2 min. and cooled on ice. Three µl of the mixture were loaded onto a 6% denaturing polyacrylamide gel and electrophoresed for 1 hr on an ABI 377 sequencer (Perkin Elmer) at 1000 volts, 60 mA, 200 W, and a gel temperature of 45 °C. Since a TAMRA labeled GeneScan Molecular

25 size standard 500 was loaded on the same gel, the molecular weight of cleavage products could be estimated by comparison to the mobility of size standard using the GeneScan analysis software versions 2.1 or 3.0a.

Figure 14 shows the amount of cleavage products for the different ratios of mutant-to-wild type DNA. The peak area was measured by the GeneScan software

30 (v. 3.0) and was used for determining the relative fluorescence intensity. Cleavage signals generated wild type homoduplex were used as wild type controls. Background intensity was determined by measuring signal intensities directly above and below the

cleavage band for both top and bottom strand products, respectively. The background signals were then averaged from seven samples with different ratios and one wild type sample. The peak area associated with the cleavage product was determined by analysis with GeneScan Analysis software 3.0. Bar graphs in Figure 14 indicate the relative

5      fluorescence intensity with their respective mutant-to-wild type ratios. (Striped bar: top strand cleavage products; solid bar: bottom strand cleavage products.) The average background signals are indicated with a horizontal dashed line. (Bkdg-top stands for background signals for the average top strand cleavage products, bkdg-bottom stands for the average background signals for bottom strand cleavage products.) The mutation,

10     nucleotide change, and the mismatch base pairs are indicated inside the graph.

These results indicate that the present invention is able to consistently distinguish cleavage signals from background signals in mutant to wild-type DNA ratios of at least 1:20 for all three mutants. The present invention has been able to detect cleavage signals in mutant to wild-type DNA ratios as high as 1:50, but this has

15     not been observed in all cases studied. Therefore, the present invention is limited to a sensitivity of 1:20 (mutant-to-wild type DNA).

### Example 19 – Detection of Small Deletion, Insertion in *BRCA1*, *BRCA2*, and *VHL* Genes

20

In order to determine the ability of the present invention to detect small deletion or insertions, it was applied to samples containing an AG deletion in exon 2 or a C insertion in exon 20 of *BRCA 1*, a T deletion in exon 11 of the *BRCA 2* gene, or either an AGA insertion or an A deletion in exon 2 of von Hippel Lindau (*VHL*) gene.

25     The sequence of PCR primers for amplifying exon 2 and 20 in *BRCA1*, exon 11 in *BRCA2* and exon 2 in *VHL* are listed in Table 2A, and PCR thermocycle conditions are listed in Table 2B. Since the mutations are heterozygous in the sample, it was not necessary to add wild-type PCR fragments. In order to remove *Taq* DNA polymerase, 1 µl of proteinase K was added (20 mg/ml, QIAGEN) for every 12 µl of

30     PCR products. This reaction was incubated at 70 °C for 10 min and at 80 °C for 10 min to inactivate the Proteinase K. Heteroduplex fragments were then formed by heating the mixture at 94 °C for 1 min, 65 °C for 15 min, and then cooling down to room temperature.

For the cleavage reaction, the standard reaction mixture consisted of 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM MgCl₂, 5% DMSO, 1.5 M betaine, 100 ng PCR products, and 500 nM purified *Tma* endonuclease V protein. The reaction mixture was incubated at 65°C for 1 hour and was terminated by adding

5     15 µl of reaction mixture to 2 µL of 10x ligase supplemental buffer (200 mM Tris-HCl, pH 8.5, 12.5 mM MgCl₂, 500 mM KCl, 100 mM DTT, and 200 µg/ml BSA). Next, 1 µl of 20 mM NAD⁺ and 2 µl of 60 nM AK16D DNA ligase were added to bring the final concentration of the ligase reaction mixture to 20 mM Tris-HCl pH 7.6, 5 mM MgCl₂, 50 mM KCl, 10 mM DTT, 1 mM NAD⁺, 20 µg/ml BSA and 6 nM

10    AK16D DNA ligase. The mixture was incubated at 65 °C for 20 min and terminated by adding an equal volume of GeneScan stop solution (50 mM EDTA, 1% blue dextran and 80% formamide). The reaction mixture was then heated at 94°C for 2 min. and cooled on ice. 3 µl of the mixture were loaded onto a 6% denaturing polyacrylamide gel and electrophoresed for 1 hr on an ABI 377 sequencer (Perkin

15    Elmer) at 1000 volts, 60 mA, 200 W, and a gel temperature of 45 °C. Because a TAMRA labeled GeneScan Molecular size standard 500 was loaded on the same gel, the molecular weight of cleavage products could be estimated by comparison to the mobility of size standard using the GeneScan analysis software versions 2.1 or 3.0a.

The gel image showed that the cleavage of the AG deletion mismatch

20    of *BRCA 1* was very strong, but the cleavage bands associated with the C insertion of *BRCA 1* and the T deletion of *BRCA 2* are faint (Figure 15). A non-specific band below the cleavage band of the T deletion was removed after ligation, which indicates that non-specific nicks can be sealed by the ligase. For the *VHL* gene, the cleavage of the AGA insertion is very strong, and the cleavage of an A insertion is also good

25    (Table 4). These results demonstrate that endoV can recognize and cleave a two to three nucleotide insertion or deletion efficiently. It also can detect a one nucleotide insertion or deletion, but the efficiency was observed to be less than that of a two or three nucleotide change.

A comparison of lanes 13-18 with lanes 19-24 demonstrate the

30    advantages of using a DNA ligase step for distinguishing point mutations in the p53 gene when using clinical samples. Significant background signal in lanes 13-18 is all but eliminated in lanes 19-24 allowing for unambiguous detection of mutant signals.

**Example 20 - Detection of Mutations in Long PCR Fragments**.

The ability of the present invention to mutation scan on longer PCR

5    fragments was determined using a 1.7 kb PCR fragment from the *p53* gene. The

sequences of the PCR primers used to amplify this 1.7 kb segment are listed in

Table 2A, while PCR thermocycle conditions are listed in Table 2B. In order to

remove *Taq* DNA polymerase, 1 μl of proteinase K was added (20 mg/ml, QIAGEN)

for every 12 μl of PCR products. This reaction was incubated at 70°C for 10 min and

10   at 80°C for 10 min to inactivate the Proteinase K. Heteroduplex fragments were then

formed by heating the mixture at 94°C for 1 min, 65°C for 15 min, and then cooling

down to room temperature. The PCR fragments were then washed twice with 10 mM

Tris pH 7.5 and excess dNTP and primers were removed by a Microcon 30ˈfilter

(Millipore) centrifugation step before endoV cleavage reaction. This resulted in the

15   buffer condition changing and the volume being reduced to half of the original

volume before washing. Therefore, the DNA concentration was increased two fold to

about 10-20 ng/μl. The *Tma* endoV cleavage reaction was performed at 65°C for 1

hour in the buffer containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 200

ng PCR heteroduplex fragments, 5 mM $MgCl_2$, 1.5 M betaine, 2% DMSO, and 500

20   nM *Tma* endoV. After the endoV reaction, the fragments were washed again to

remove betaine and DMSO. The ligation was performed at 65°C for 20 min in the

presence of 1-6 nM *Tsp*. AK16D ligase in a buffer containing 20 mM Tris-HCl

(pH7.6), 5 mM $MgCl_2$, 50 mM KCl, 10 mM DTT, 1 mM $NAD^+$, and 20 μg/ml BSA.

This procedure was performed using genomic DNA containing *p53*

25   R248W (C→T) as the template, and 400 bp, 800 bp, 1.2 kb and 1.7 kb fragments

containing the R248W mutation were amplified. This assay demonstrates that the

invention can detect mutations in PCR fragments up to 1.7 kb in size and potentially

higher (Figure 16). Top strand cleavage (TET labeled) was also observed in these

assays.

30

**Example 21 - Micro DNA Sequencing To Detection Of *P53* R248w(C→T).**

   The strategy of micro-DNA sequencing is illustrated in Figures 16A
and 18A. The DNA fragment containing *p53* R248W(C→T) was PCR amplified with

5 unlabeled primers. The sequences of PCR primers are listed in Table 2A, and the
PCR thermocycle conditions are listed in Table 2B. PCR fragments containing *p53*
R248W(C→T) were mixed with equal amounts of wild type PCR fragments. In order
to remove *Taq* DNA polymerase, 1 µl of proteinase K was added (20 mg/ml,
QIAGEN) for every 12 µl of PCR products. This reaction was incubated at 70°C for

10 10 min and at 80°C for 10 min to inactivate the Proteinase K. Heteroduplex
fragments were then formed by heating the mixture at 94°C for 1 min, 65°C for 15
min, and then cooling down to room temperature. The PCR fragments were then
washed twice with 10 mM Tris pH 7.5 and excess dNTP and primers were removed
by a Microcon 30 filter (Millipore) centrifugation step before endoV cleavage

15 reaction.

   The *Tma* endoV cleavage reaction was performed at 65°C for 1 hour in
the buffer containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 200 ng PCR
heteroduplex fragments, 5 mM MgCl$_2$, 1.5 M Betaine, 2% DMSO, and 500 nM *Tma*
endoV. After the endoV reaction, the fragments were washed again to remove

20 betaine and DMSO. The ligation was performed at 65°C for 20 min in the presence of
1-6 nM *Tsp*. AK16D ligase in a buffer containing 20 mM Tris-HCl (pH7.6), 5 mM
MgCl$_2$, 50 mM KCl, 10 mM DTT, 1 mM NAD$^+$, and 20 µ/ml BSA. After ligation,
the mixture was incubated at 65°C for 20 min and then washed to remove salts.

   The nicked heterduplex products were excised several nucleotides back

25 from the nick 3' → 5' with DNA polymerase I Klenow fragment. The reaction
mixture (40 µl) contained 120 ng DNA from the ligation reaction, 1x *E. coli*.DNA
polymerase I buffer, and 20 units DNA polymerase I Klenow fragment. The mixture
was incubated at 37°C for 30 min. The product of this reaction was subsequently
used as substrate for a sequencing reaction.

30    The DNA sequencing reaction contained 30 ng DNA from the Klenow
fragment reaction, 20 µM dNTP, 20 µM ddGTP, 224 µM ddTTP, 22 µM ddATP, 32
µM ddCTP, 1x sequencing buffer, and 1 µl of *Taq* DNA polymerase FS (Perkin

Elmer lot # 361451005). The ratio of the four dideoxynucleotide
(A:C:G:T=0.11:0.16:0.10:1.12) was taken from Rosenblum, B. B. et al., "New Dye-
Labeled Terminators for Improved DNA Sequencing Pattern," Nucleic Acids Res.
25:4500-4 (1997), which is hereby incorporated by reference. The reaction mixture

5    was incubated at 60°C for 30 sec using PE GeneAmp PCR system 2400
thermocycler. The excess BigDye dideoxynucleotide was removed by loading the
reaction mixture on a Centri-Sep™ spin column P/N CS-90 (Princeton Separation,
Adelphia, NJ) and microcentrifuged at 3000 rpm for 2 min. Five µl of the eluate was
added to an equal volume of GeneScan stop solution (50 mM EDTA, 80%

10   formamide, and 1% blue dextran). After heating at 94°C for 2 min, 1 µl of the
mixture was loaded on a 10% denaturing polyacrylamide gel and electrophoresed at
1000 volts, 60 mA, 150 W, and a gel temperature of 45°C. Running time took
approximately 4 hours. The Run Module was set to filter E and the Matrix was set to
dRhodamine Matrix. The data was analyzed with GeneScan analysis (v.3.0a). See

15   Figure 16B.

For comparison of the sequence results, standard dRhodamine DNA
cycling sequencing was also performed. The DNA template for this sequencing
reaction was PCR product which was amplified with unlabeled PCR primers. The
sample was then washed twice with 10 mM Tris pH 7.5 and excess primers were

20   removed by a Microcon 30 filter (Millipore) centrifugation step. One of the
unlabelled PCR primers was then added to be used as a sequencing primer. Standard
DNA sequencing was performed using an ABI Prism dRhodamine Terminator Cycle
Sequencing Ready Reaction Kit (Perkin Elmer). Twenty µl of the reaction mixture,
containing 8.0 µl of terminator ready reaction mix, 6.0 µl of PCR products (10 ng/l),

25   1.0 µl of each PCR primer (3.2 µM), and 7 µl of ddH$_2$O, was incubated in a PE Gene
Amp PCR System 2400 thermocycler for 25 cycles of 96°C for 10 sec, 50°C for 5
sec, and 60°C for 4 min. After the reaction, the mixture was precipitated by adding 2
µl of 3 M NaAc (pH 4.6) and 50 µl of 95% ethanol, it was placed on ice for 10 min.
After microcentrifuging for 15-20 min at maximum speed, the pellets was rinsed with

30   70% ethanol and dried. The pellet was then suspended in 4 µl of DNA sequencing
loading buffer (5 mM EDTA, 1% blue dextran, and 80% formamide). After heating

at 95°C for 2 min., 1-2 μl of the mixture was loaded on a 10% polyacrylamide

denaturing gel (small plate) and electrophoresed at 1000 volts, 60 mA, 150 W, and a

gel temperature of 45°C. Running time was approximately 4 hours on an ABI DNA

sequencer 377. The Run Module was set to filter E, and Dye Set/ Primer File was set

5    to DT{dR Set Any-primer}. The sequencing patterns were analyzed with DNA

sequencing analysis software (v. 3.0)(see Figure 18).

The sequence results for the bottom strand are shown in Figure 18 B

(micro-DNA sequencing) and Figure 18C (standard DNA sequencing). The position

where G (blue color) and A (green color) peaks overlap indicates the position of the

10    mismatch, and shows that the mutation is G→A (C→T for the top strand).

### Example 22 - Detection of *K-ras* G12V Mutation in PCR Fragments Containing 7-deaza-dGTP.

15    In order to explore the possibility of using nucleotide analogues with

*Tma* endonuclease V, the same concentration of 7-deaza-dgtp was used instead of

regular dgtp in PCR reaction mixture. The PCR reaction was setup to amplify *k-ras*

exon-1 using genomic DNA from a cell line containing wild type DNA (ht29) and

mutant DNA g12v(g→t) (sw620). The PCR primers and PCR program, *Tma* cleavage

20    and *Tsp*.DNA ligation conditions were the same as the standard conditions. To

compare the cleavage products from the PCR fragment containing 7-deaza-dgtp, the

cleavage products from PCR fragments containing regular dgtp were also loaded on

the same gel.

The 7 position in 7-deaza-dGTP is a carbon instead of nitrogen

25    (Figure 17A). The PCR reaction was setup to amplify K-*ras* exon-1 using genomic

DNA from cell line containing wild type DNA (HT29) and mutant DNA G12V(G→T)

(SW620). In comparison to the cleavage products from the PCR fragment containing

7-deaza-dGTP, the cleavage products from PCR fragments containing regular dGTP

were also loaded on the same gel. For the heteroduplex PCR fragment containing 7-

30    deaza-dGTP, cleavage of the top strand containing (G→T) mutation was inhibited,

while cleavage of the bottom strand containing (C→A) is still present (Figure 17B).

This result indicated a possible contact between *Tma* endonuclease V and N-7 in

Guanine. While the use of 7-deazaG did not allow for cleavage of the refractory

G13D mutation, the concept of lowering the stability of G-C base pairs by using a non-cleavable analogue was shown to be robust. Several additional (non-specific) cleavage products are observed in the second lane containing deazaG. Alternative analogues may be considered, especially those which base pair with guanosine but destabilize hybridization, such as 2-pyrimidinone instead of cytosine.

## Example 23 - Mutant Endonucleases.

Wild type *Thermotoga maritima* Endo V can identify approximately 98% of the SNPs found in the human genome. To identify the remaining SNPs, or to achieve a more robust signal on existing SNPs or mutations, modified or novel EndoV enzymes may be required. This may be achieved by either introducing mutation(s) into *Thermotoga maritima* Endo V to alter its mismatch base specificity or by utilizing an Endo V from a different organism that has a different mismatch base specificity. A mutant *Thermotoga maritima* EndoV or an alternate Endo V could be used in the same reaction with wild-type *Thermotoga maritima* Endo V, to expand the repetoire of sequences which can be recognized in this assay.

Primary sequence alignment of different eukaryotic, prokaryotic, and archea EndoV orthologs revealed a few residues which appeared to be evolutionarily conserved. Nine different site–specific mutants (D43A, Y80A, R88A, E89A, D105A, D110A, H116A, H125A and , K139A ) were constructed, and 5 of these (Y80A, R88A, E89A, H116A, and K139A) appear to have useful altered specificity (See Table 7).

**Table 7.** Summary of enzymatic and binding activity of Tma EndoV mutants.

| Tma endoV Mutants | wt | D43A | Y80A | R88A | E89A | D105A | D110A | H116A | H125A | K139A |
|---|---|---|---|---|---|---|---|---|---|---|
| Cleavage | I/A | | | | | | | | | |

| Predictions | wt | Catalytic Mg binding | Stacking | O2, O6 H-bond Accept.? | N1 H-bond Doner? | wt | Catalytic Mg binding | O2,6,N7 H-bond Accept.? | Almost wt | O2,6,N7 H-bond Accept.? |

5      In addition, this analysis identified two aspartates, D43 and D105, as being the

catalytic residues for this enzyme.

The approach used to develop useful *Thermotoga maritima* Endo V

mutants is based on creating site-directed mutants at positions that are involved in

protein-substrate interactions. *Thermotoga maritima* Endo V demonstrates

10     significantly greater cleavage activity with inosine or uracil within either a matched or

mismatched substrate, as compared with mismatches containing the naturally

occuring deoxyribonucleotide bases (dA, dC, dG, and dT). Therefore, one can

increase the relative specificity of the enzyme for a natural base by decreasing the

specificity of the enzyme for inosine or uracil, and/or increasing the specificity for a

15     natural base.

Protein specificity for a substrate typically involves interactions

between amino acid side chains of the enzyme and the functional groups of the

substrate. Interactions involving amino acid side chains and substrate moieties of

different chemical composition (e.g. hydrophobic/polar interactions) greatly

destabilize substrate binding and can dramatically decrease the ability of an enzyme to utilize a specific substrate. Since the enzyme functions *in vitro* with dramatically higher activity with inosine and uracil containing substrates and the natural occurring deoxyribonucleotide bases are less favorably cleaved, this strongly suggests one or

5  more destabilizing interactions associated with a natural base. Therefore, by mutagenizing the enzyme at positions of enzyme-mismatch base interactions, the specificity of the enzyme can be altered to favor naturally occurring deoxyribonucleortide bases. A similar approach has been successful with human UDG, which recognizes uracil within DNA substrates. Kavli et al., The EMBO

10  Journal 15:3442-47 (1996), which is hereby incorporated by reference.

Residues that are involved directly in protein-substrate interactions have a strong tendency to be conserved among enzymes of the same family. Therefore, in a primary amino acid sequence alignment, highly conserved residues represent good candidates for mutagenesis. In order to identify positions in

15  *Thermotoga maritima* Endo V suitable for mutagenesis, the ClustalW alignment algorithm with a PAM250 Residue Weight Table(Pairwise Alignment Parameters: Ktuple = 1, Gap Penalty = 3, Window = 5, and Diagonals Saved = 5; Multiple Alignment Parameters: Gap Penalty = 10 and Gap Length Penalty = 10) was used to perform a primary amino acid sequence alignment among 13 identified and putative

20  Endo V enzymes from thermophilic and mesophilic archeabacteria and eubacteria (i.e. *Thermotoga maritima* (SEQ. ID. No. 37), *Pyrobaculum aerophilum* (SEQ. ID. No. 38), *Pyrococcus horikoshii* (SEQ. ID. No 39), *Pyrococcus abyssi* (SEQ. ID. No. 40), *Pyrococcus furiosus* (SEQ. ID. No. 41), *Archaeoglobus fulgidus* (SEQ. ID. No. 42), *Aeropyrum pernix* (SEQ. ID. No. 43), *Clostridium acetobutylicum* (SEQ. ID.

25  No. 44), *Yersinia pestis* (SEQ. ID. No. 45), *Escherichia coli* (SEQ. ID. No. 46), *Bacillus subtilis* (SEQ. ID. No. 47), *Salmonella typhimurium* (SEQ. ID. No. 48), and *Streptomyces coelicolor* (SEQ. ID. No. 49) (Figure 19)). Since the majority of enzymes utilized in the alignment are putative Endo V enzymes, the mismatch specificity of most of these enzymes is unknown. As a result, when utilizing the

30  alignment to identify candidate residues in *Thermotoga maritima* Endo V, one can either assume that the homologous enzymes have similar or different specificities. If one assumes similar specificities, then residues that are highly conserved for the

majority of Endo V provides candidates. Whereas if one assumes different specificities, then positions where there exists two sets of highly conserved residues represent candidates.

In analysis assuming similar mismatch specificity among the family of endo Vs, 12 residues (D43, F46, Y80, R88, E89, D105, D110, H116, R118, H125, K139, and F180) in *Thermotoga maritima* Endo V have been identified that were 1) highly conserved for the majority of Endo V enzymes and were 2) best suited for mutagenesis. Although aliphatic hydrocarbon chains (i.e. L, I, V, and M residues) can play a role in protein-substrate interactions, positions of high conservation with these residues are not listed, since they can also play a role in stabilizing the hydrophobic core of the enzyme. In addition, highly conserved prolines and glycines should be avoided for mutagenesis due to the unique chemical and structural influences associated with these amino acid residues. From the initial set of 12, 9 different site–specific mutants (D43A, Y80A, R88A, E89A, D105A, D110A, H116A, H125A and, K139A) and 5 of these mutant endo Vs (Y80A, R88A, E89A, H116A, and K139A) appear to have useful altered specificity. These results demonstrate that the present invention is useful for identifying *Thermotoga maritima* EndoV positions to mutate in order to confer altered specificity. Since the chemical nature of the polar group (e.g., hydrogen bond donor vs. hydrogen bond acceptor) can also have a strong influence on substrate specificity, further mutations at these positions can facilitate the generation of a mutant Endo V enzymes that extend the capabilities of the current invention (Table 8).

**Table 8:  EndoV Mutants, Group 1.**

5

In the examples provided *infra*, substituting an alanine would be predicted to remove destabilizing residues for a naturally occuring base at a mismatch.  Alternatively, altering a charged polar residue with a pure hydrophobic residue may increase the stability or binding affinity of a naturally occuring base at a mismatch.  In addition,

10    changing a residue from a positive to negative charge may alter the specificity of the enzyme, such that a natural base at a mismatch is preferred.  Since interactions between substrate and enzyme may involve complex hydrogen bond networks, altering two or more of the residues listed in Table 7 may be required to obtain better activity of the enzyme to mismatches containing natural bases.  Further, subtle

15    changes in the catalytic residues, such as D43E or D105E, may assist in catalysis of naturally occuring base at a mismatch.

In analysis assuming dissimilar mismatch specificity among some members of the EndoV family, 2 residues (G83 and I179 ) were identified that contain two separate sets of conserved sequence.  For example, the residues homologous to

20    I179 of *Thermotoga maritima* Endo V, are either a polar-charged residue (K) or an aliaphatic residue (L, I, or V).  If this position is involved in making an interaction

with a DNA base at the mismatch, the composition of the residue (polar and charged vs. hydrophobic) would influence which substrates are preferred. The conserved set different from *Thermotoga maritima* endo V at the given position as the basis for initial mutagenesis (e.g., I179K) (Table 9) was used.

**Table 9: EndoV Mutants, Group 2.**

|  | Remove Destabilizing Residue | Add Stabilizing Residue | Modify Stability |
|---|---|---|---|
| G83 |  | **G83(T,S)** G83(N,Q) G83(D,E) G83(R,K) G83A G83(L,I,V,M) |  |
| I179 | **I179A** | **I179(R,K)** I179(N,Q) I179(D,E) I179(T,S) |  |

In addition to developing mutant *Thermotoga maritima* Endo V enzymes, the cloning of other thermostable Endo V enzymes provides a source of alternative, but functionally similar, enzymes for use in the present invention. This invention is capable of utilizing other thermostable EndoV enzymes, or other endonucleolytic enzymes as long as the products are compatible with the thermostable ligase step of the invention. By utilizing a themostable Endo V with different substrate specificities from *Thermotoga maritima* Endo V, the capabilities of the present invention can be further extended.

**Example 24 - Mutation Scanning Using a Combined EndoV/DNA Ligase Assay.**

An analysis of p53 mutations in colon tumor DNA using a combination of both PCR/LDR/array and EndoV/Ligase mutation scanning proved superior to automated sequencing (see Table 10). Of 23 samples shown to have 26 p53 mutations by PCR/LDR combined with EndoV/ ligase, 8 samples were missed by automated sequencing (65% true positive, 35% false negative). Mutation detection in five samples called positive with EndoV/Ligase mutation scanning, required gel

purification of PCR fragments, and re-sequencing of both strands with manual reading.  Significantly, EndoV/Ligase mutation scanning scored all four frameshift mutations, which accounts for almost 20% of the samples with p53 mutations.  Such frameshift mutations are beyond the detection capacity of commercially available p53 hybridization chips.

**Table 10:** **Detecting p53 mutations in tumor samples: Comparisons of using a combined analysis with PCR/LDR and EndoV/ligase mutation scanning to Dideoxysequencing.**

\* Required gel purification of PCR product to obtain sequencing result.

\# Sequencing of 5 random samples of 27 called negative by PCR/LDR and EndoV/Ligase reveal no new mutations.

Mixing experiments using three different K-*ras* mutations demonstrated that the Endo V/ ligase reaction is also a sensitive assay: mutation can be detected above background when 1 mutant sequence is diluted with 20 wild-type sequences.

The colon tumor DNA was isolated from non-microdissected samples, with stromal cell infiltration from about 10%-50%. Mutation of one p53 allele is

invariably accompanied by loss of heterozygosity ("LOH") of the other allele,
occuring either through chromosome loss or through mitotic nondisjunction (i.e. both
mutant chromosomes migrate to the daughter cell). Thus, DNA from the above
samples would have a range of mutant p53: wild-type allele of from about 90%:10%

5      (for nondisjunction with 10% stroma) to 33%:67% (for chromosome loss with 50%
stroma). When the above samples were reanalyzed for p53 mutations in pools of 3
samples, the EndoV mutation scanning assay could still identify the presence of all
the mutants. Several of the pooled sample bands were even stronger than from
individual samples (suggesting the original sample was mostly mutant DNA), while a

10     few bands were weaker but could still be detected (suggesting the original sample had
substantial stromal contamination). The ability to detect mutations in pools of 5 or
even 10 samples would significantly improve cancer mutation scoring.

**Example 25 - Site-Directed Mutagenesis of Tma EndoV.**

15
                Alanine scanning mutagenesis was performed at nine conserved
positions of *Thermotoga maritima* endoV to identify amino acid residues important
for its endonuclease activity (Table 11). Alanine substitution at the DDE motif
residues D43, E89, D110, abolish or substantially reduce inosine cleavage activity.

20     These mutants also gain binding affinity to double-stranded or single-stranded inosine
substrate in the absence of a metal ion, suggesting that these residues are involved in
the coordination of catalytic $Mg^{2+}$. Y80A, H116A, and, to a lesser extent, R88A,
demonstrate reduced affinity to double-stranded or single-stranded inosine substrate
or nicked product. The lack of tight binding to nicked inosine product accounts for an

25     observed increase in turnover of inosine substrate since the product release is less
rate-limiting. Y80A, R88A, K139A, and, to a lesser extent, H116A show reduced
activity towards AP and uracil substrates. Consistent with their location in or near the
base recognition pocket, these residues may play a role in substrate recognition.

**Table 11. DNA Cleavage Activity of Nine *Tma* Endov Mutants[a]**

| Tma EndoV Mutants | wt | D43A | Y80A | R88A | E89A | D105A | D110A | H116A | H125A | K139A |
|---|---|---|---|---|---|---|---|---|---|---|

[a] The cleavage reactions were performed at 65°C for 30 minute in a 20 μl reaction mixture containing 10 mM HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM MgCl$_2$, 10 nM DNA substrate, 100 nM purified Tma endoV mutants. The reactions were terminated by adding an equal volume of GeneScan stop solution. The reaction mixtures were then heated at 94°C for 2 min. and cooled on ice. Three microliters of samples were loaded onto a 10% GeneScan denaturing polyacrylamide gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an ABI 377 sequencer (Perkin Elmer). ss I: single stranded inosine-containing substrate. The number of plus signs represents the extent of cleavage of inosine-, uracil-, or AP site-containing strand. (+++) = about 10%; (++) = about 5%; (+) = about 2%; (-) no cleavage observed.

Site-specific mutagenesis was used to generate additional mutations at R88 (-→K, Q, E), H116 (-→Q, T, E), and K139 (-→Q, E). These mutants substantially lost activity using Mg$^{2+}$ as cofactor. Four of the mutants (R88Q, R88E, H116Q, and H116T) cleaved certain substrates in Mn$^{2+}$ better than wild-type enzyme does (See Figure 20, lanes 4 & 6 compared to lane 12, and Table 12). This result is not surprising since the mutant presumably binds the substrate less well than wild-type enzyme, and, consequently, there is less non-specific binding and cleavage. The R88Q and R88E enzymes demonstrated a stronger preference for cleaving the G base in both G:A and A:G mismatched substrate than wild-type enzyme. Significantly, the preferred cleavage site of the "G" strand is now predominantly at the 3' side of the mismatched base (See Figure 20, Lane 1 & 7, Table 12). Wild-type enzyme does not cleave the C strand in the A:C substrate, while the R88 mutant had medium level activity, with the preferred cleavage site of the "C" strand now two bases from the 3' end of the mismatch (Table 12).
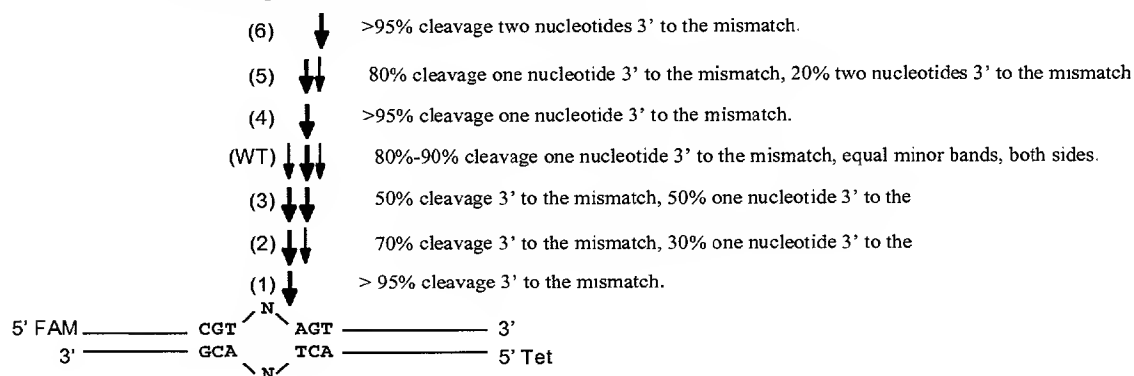

**Table 12.** Cleavage Intensities of various substrates treated with wild-type and mutant *Tma* EndoV.

| Metal/Substr. | WT | WT | R88Q | R88Q | R88E | R88E | H116Q | H116Q | H116T | H116T |
|---|---|---|---|---|---|---|---|---|---|---|
| Mn2+ | G: ++ | A: +++ | G: +++[2] | A: ++[4] | G: ++++[2] | A: ++[4] | G: +[1] | A: ++++ | G: | A: +++[4] |

```
                    N
5' FAM _____ CGT   AGT _____ 3'
3' _____ GCA   TCA _____ 5' Tet
                    N
```

Superscripts (1-6) indicate cleavage patterns and relative intensities. No superscript indicates cleavage pattern was similar to wild-type (WT) enzyme. Overall cleavage intensities estimated based on uncut starting substrate. (++++) = about 30%; (+++) = about 20%; (++) = about 10%; (+) = about 5%; (w) = about 2%.

Both Tma EndoV H116Q and H116T exhibited almost exclusive activity towards adenosine containing substrates (Figure 20, Table 12, lanes 4 and 6), with cleavage at the correct penultimate position. There was almost no activity towards the "G" containing strand, suggesting these mutant enzymes are the first step towards development of stronger enzymes for specific mismatched sequences. The change in cleavage site for the R88 and H116 mutants suggests significant plasticity in binding specific mismatched DNA by variant enzymes, further emphasizing the

need for multiple crystal structures to understand non-classical cleavage for specific mismatches.

### Example 26 - Alanine Scanning Mutagenesis

An overlapping extension PCR procedure was used for site-directed mutagenesis (Ho, S. et al., Gene 77:51-59 (1989), which is hereby incorporated by reference in its entirety). PCR products digested with a pair of *Nde*I and *Spe*I were ligated to cloning vector pEV5 treated with the same pair of restriction endonucleases. The ligated vectors were transformed into *E. coli* strain AK53 (*mrr*B⁻, MM294). Plasmids containing inserts were reisolated and sequenced on a ABI sequencer using Dye-dideoxy terminator chemistry to identify mutated sequence and ensure that the constructs were free of PCR error. Strains containing mutated Tma endonulcease V (*nfi*) genes were expressed in 5 ml of MOPS medium supplemented with 50 μg/ml ampicillin (Neidhart, F.C., et al., J. Bacteriol. 119(3):736-47 (1974), which is hereby incorporated by reference in its entirety) at 37°C overnight. Cell pastes were suspended in 300 μl of sonication buffer and sonicated 4 x 10 sec at 4°C using a Sonifier Cell Disruptor 350 (Branson). After removing cell debris by centrifugation, the supernatants containing Tma endonuclease V proteins were incubated at 70°C for 15 min to inactivate host proteins. The denatured proteins were separated from soluble Tma endonuclease V proteins by centrifugation. The protein concentrations of Tma endonuclease V mutants were quantified by scanning a 12.5% SDS-PAGE gel loaded with known amounts of wild-type Tma endonuclease V. Partially purified proteins were diluted to 1 μM with 1 x *Taq*I storage buffer and stored at -20°C prior to use.

### Example 27 - DNA Cleavage Reaction For Assaying Variant Endonucleases.

The fluorescence labeled deoxyoligonucleotide substrates were prepared as described (Huang, J., et al., Biochemistry 40(30):8738-8748 (2001), which is hereby incorporated by reference in its entirety). The sequence of a typical inosine substrate (SEQ. ID. Nos. 50-51, respectively) is as follows:

```
                                                    ↓
5'-Fam-TA CCC CAG CGT CTG CGG TGT TGC GT   1 AGT TGT CAT AGT TTG ATC CTC TAG TCT TGT TGC GGG TTC C-3'
3'- GGG GTC GCA GAC GCC ACA ACG CA   1 TCA ACA GTA TCA AAC TAG GAG ATC AGA ACA ACG CCC-Tet-5'
                                 ↑
```

A nick event at the top strand generates a 27 nt labeled product while that at the

bottom strand generates a 38 nt labeled product. The cleavage reactions were

5    performed at 65°C for 30 minute in a 20 μl reaction mixture containing 10 mM

HEPES (pH 7.4), 1 mM DTT, 2% glycerol, 5 mM MgCl$_2$ unless otherwise specified,

10 nM DNA substrate, indicated amount of purified Tma endonuclease V protein.

The reaction was terminated by adding an equal volume of GeneScan stop solution.

The reaction mixtures were then heated at 94°C for 2 min and cooled on ice. Three

10    microliter of samples were loaded onto a 10% GeneScan denaturing polyacrylamide

gel (Perkin Elmer). Electrophoresis was conducted at 1500 voltage for 1 hr using an

ABI 377 sequencer (Perkin Elmer). Cleavage products and remaining substrates

quantified using the GeneScan analysis software versions 2.1 or 3.0.

15    **Example 28 - Gel Mobility Shift Assay.**

The binding reaction mixture contains 100 nM double stranded

fluorescence-labeled oligonucleotide DNA substrates, 5 mM MgCl$_2$ or CaCl$_2$ or 2

mM EDTA, 20% glycerol, 10 mM HEPES (pH 7.4), 1 mM DTT, and 75 nM of Tma

20    endonuclease V protein. The binding reactions were carried out at 65°C for 30 min.

Samples was electrophoresed on a 6% native polyacrylamide gel in 1 x TB buffer

supplemented with 10 mM MgCl$_2$ or CaCl$_2$ or 2 mM EDTA. The bound and free

DNA species were analyzed using FluorImager 595 (Molecular Dynamics) with the

following settings: PMT at 1000 Volt, excitation at 488 nm, emission at 530 nm

25    (Filter 530 DF30). Data analysis was carried out using ImageQuaNT v4.1 (Molecular

Dynamics).

**Example 29 - DNA Cleavage By Variant Endonucleases.**

30    Tma endo V mutants were generated through an overlapping PCR

procedure and partially purified through heat-treatment at 75°C for 15 min. The

resulting mutant proteins are devoid of the indigenous *E. coli* endonuclease V

(Huang, J., et al., Biochemistry 40(30):8738-8748 (2001), which is hereby

incorporated by reference in its entirety). The cleavage assays were performed using oligonucleotide substrates fluorescently labeled at both strands. Previous studies have shown that the wild-type Tma endo V nicks at inosine sites. When the enzyme is in excess, it cleaves the complementary strand opposite of the inosine-containing strand

5    (Huang, J., et al., Biochemistry 40(30):8738-8748 (2001), which is hereby incorporated by reference in its entirety). As expected for the wild-type control, a blue band was observed which represented the top inosine cleavage product and a green band which represented the bottom complementary strand cleavage product (Figure 21A). Some lower molecular weight nonspecific cleavage products were also

10   observed. D43A and D110A lost DNA endonuclease activity for cleaving either of the strands. E89A exhibited limited cleavage of the inosine strand with no detectable cleavage of the complementary strand. Y80A, R88A, H116A, and K139A maintained wt level cleavage activity towards inosine strand but lost complementary strand cleavage activity. D105A and H125A essentially maintained wt cleavage activity

15   toward both the inosine-containing strand and the complementary strand in the double-stranded substrate (Figure 21A-C). $Mn^{2+}$ enhanced non-specific cleavage activity but the overall cleavage profiles of the mutants remained similar to $Mg^{2+}$ (Figure 21B-C).

20   **Example 30 - Binding to Inosine Substrate By Variant Endonucleases.**

A fluorescence-based gel mobility shift assay was used to compare substrate binding among the nine alanine-substituted mutants (Huang, J., et al., Biochemistry 40(30):8738-8748 (2001), which is hereby incorporated by reference in

25   its entirety). As previously reported, the wt Tma endo V did not form a stable complex with the inosine substrate in the absence of a metal cofactor ((Huang, J., et al., Biochemistry 40(30):8738-8748 (2001), which is hereby incorporated by reference in its entirety) and Figure 22A). Interestingly, the two catalytically inactive mutants D43A and D110A now formed a distinct complex with the inosine substrate.

30   Although not observed in most mutational studies performed on endonucleases, the restriction endonuclease *MunI* does show such a peculiar property, i.e., elimination of the negative charges at some metal binding residues confer binding specificity to the cognate sequence (Lagunavicius, A., et al., Biochemistry 36(37):11086-11092 (1997),

which is hereby incorporated by reference in its entirety). It is suggested that the negative charges may cause electrostatic repulsion between the carboxylates and the phosphate in the absence of a neutralizing metal ion. By substituting the negatively charged Asp or Glu with Ala, the mutants become capable of binding to the cognate

5     sequence even without a metal ion. A similar notion can be applied to explain the binding behavior of D43A and D110A mutants, which implies that D43A and D110A are involved in the coordination of a divalent metal ion required for catalysis.

In the presence of a metal cofactor such as $Mg^{2+}$ or $Ca^{2+}$, most of mutants showed a binding affinity to the double-stranded inosine substrate

10    comparable to that of the wt enzyme (Figure 22B). Since $Ca^{2+}$ only supports binding but not catalysis (Huang, J., et al., Biochemistry 40(30):8738-8748 (2001), which is hereby incorporated by reference in its entirety), the shifted bands represent an ES (enzyme-substrate) complex. The shifted bands observed with $Mg^{2+}$, on the other hand, may represent an enzyme-nicked product complex due to strand cleavage.

15    Apparently, Y80A and H116A no longer bind to the intact inosine substrate at tightly as the wt enzyme as judged by gel shift data with $Ca^{2+}$ (Figure 22B). Further, the gel shift data with $Mg^{2+}$ suggested that Y80A and H116 may have reduced binding affinity to the nicked product as well (Figure 22C). To more definitively assess the impact of alanine-substituted mutants had on endonuclease binding to the nicked

20    product, gel mobility shift analysis was performed using a synthesized inosine oligonucleotide substrate with a preexisting nick (Figure 23). It is evident from the gel shift experiments with $Ca^{2+}$ that Y80A, R88A, and H116A failed to bind to the nicked inosine product as tightly as the wildtype (i.e.wt) enzyme (Figure 23A). Using the catalytically competent metal ion $Mg^{2+}$ as the metal cofactor, H116A bound the

25    nicked inosine product about half as tightly as the wt enzyme (Figure 23B). Y80A did not maintain bound to the nicked product with a long enough half-life to allow the detection of a distinct band shift (Figure 23B-C). These results suggested that some endo V variants such as Y80A and H116A may have affected both ES and EP binding, while R88A may primarily have affected product release.

30         A time course analysis was performed to assess how the altered binding behavior changed cleavage kinetics of the inosine-containing strand in a

double-stranded sequence. When the enzyme is in deficit (E:S = 1:10), the wt enzyme only cleaved a limited amount of the substrate as it remained bound to the nicked product (Figure 24). Likewise, the mutant H125A, which showed wt level cleavage activity and binding affinity, also failed to turnover this inosine-containing double-

5    stranded substrate. The three mutants Y80A, R88A, and H116A, which showed reduced affinities to the nicked inosine substrate by gel mobility shift analysis (Figures 23), now were able to release the product and nicked the inosine strand in a multiple-turnover fashion (Figure 24A). Most prominently, the cleavage reaction by Y80A proceeded close to completion with an apparent first order rate constant of 0.04

10   min$^{-1}$. The kinetic analysis, combined with the binding data, suggests that some of the mutants (as represented by Y80A) have changed the reaction kinetics by increasing the product release rate constant k3 to facilitate multiple turnover (Figure 24B).

15   **Example 31 - Cleavage and Binding of Single-Stranded Inosine Substrate By Variant Endonucleases.**

          To assess the single-stranded endonuclease activity, cleavage was examined using fluorescently labeled (Tet) inosine-containing single-stranded

20   oligonucleotide. Most of the endo V variants retained wt cleavage activity toward the single-stranded inosine-containing substrate (Figure 25A). Consistent with the cleavage results obtained using the double-stranded inosine-containing substrate (Figure 21), E89A had a significantly reduced cleavage activity, while D43A and D110A were inactive toward the single-stranded inosine-containing substrate

25   (Figure 25A). The binding of single-stranded inosine-containing substrate also required a metal cofactor for most of the mutants. D43A, D110A, and E89A, however, were able to bind to the single-stranded inosine-containing substrate without a metal ion (Figure 25B), suggesting a similar interaction among the enzyme, inosine substrate, and metal ion for both single-stranded or double-stranded substrates. The

30   formation of a distinct shifted band by E89A in the absence of a metal ion using the single-stranded inosine substrate suggests that E89 may play an analogous role in metal binding similar to D43 and D110 (Figures 22A and 25B).

The binding pattern of the single-stranded inosine-containing substrate in the presence of $Ca^{2+}$ is essentially identical to that of the double-stranded substrate, i. e., most of the mutants exhibited a binding affinity at least as strong as the wt enzyme. Y80A and H116A again showed lower affinity to the inosine substrate

5   (Figure 25C). In the presence of $Mg^{2+}$, Y80A and H116A showed an intense lower molecular weight band with concurrent disappearance of the free DNA band, suggesting that most of the single-stranded substrate were cleaved (Figure 25D). Given the reduced binding seen with $Ca^{2+}$, it is likely that these two mutants no longer bind to the single-stranded nicked product tightly, thereby dissociating from

10  the product. D43A, D110A, and E89A were unable to cleave the inosine substrate or cleave at a much reduced rate (Figure 25A). As expected, they formed a distinct stable complex as seen by mobility shift gel (Figure 25D). However, they migrated faster than the wt and other catalytically active endo V mutants. One scenario to explain the different migration patterns is that the binding of the wt enzyme and some

15  other active mutants may cause bending of the nicked inosine product (Figure 25D), resulting in a slower migration (Lane, D., et al., Microbiol Rev 56(4):509-28 (1992), which is hereby incorporated by reference in its entirety). D43A, D110A, and E89A mutants may have lost the ability to bend the DNA due to the loss of the negative charges.

20

### Example 32 - Cleavage of Uracil and AP Site Substrates By Variant Endonucleases.

Uracil endonuclease activity of Tma endo V mutants were assessed

25  using A/U, G/U, and T/U substrates. D43A, D110A, and E89A were inactive toward any of the uracil substrates, which is consistent with the proposed metal binding role (Figure 26A-C). D105A, which showed wild-type activity towards various inosine substrates, maintained essentially wild-type activity with uracil-containing substrates. H125A cleaved the G/U and T/U substrates as well as the wild-type enzyme

30  (Figure 26B-C); however, it had reduced activity against the perfectly base-paired substrate A/U (Figure 26A). Y80A had minimal uracil cleavage activity. R88A, H116A, and K139A exhibited reduced uracil cleavage. The degree of uracil cleavage by these three mutants appeared to be affected by the nature of the base-pair. When

the substrate contained a Watson-Crick base-pair such as A/U (Figure 26A), the uracil cleavage activity was lowest. When the substrate contained a mismatch such as G/U or T/U, the uracil cleavage activity was enhanced (Figure 26B-C). These results are in keeping with the previous time course analysis of the wt enzyme using A/U and

5     T/U substrates (Huang, J., et al., Biochemistry 40(30):8738-48 (2001), which is hereby incorporated by reference in its entirety), suggesting that a uracil in a locally distorted mismatch environment provides a better signal for base recognition.

    AP endonuclease activity of Tma endo V mutants was assessed using the A/AP substrate. *E. coli* endonuclease IV is a thermostable 5' AP endonuclease

10    (Ljungquist, S., J Biol Chem 252(9):p2808-04 (1977), which is hereby incorporated by reference in its entirety). To prevent the interference of the host AP endonuclease, the wt and mutant endo V were further purified by HiTrap SP column chromatography (Amersham Pharmacia Biotech). Using column purified mutant proteins, AP endonuclease activity was only observed with D105A and H125A

15    (Figure 26D), both of which had consistently showed wt DNA cleavage activities towards other substrates . Under the 65°C assay conditions, the AP substrate underwent spontanous cleavage, generating a weak background as seen in the control lane (Figure 26D). Some marginal AP endonuclease activity may be associated with H116A, but all other mutants abrogated AP cleavage.

20    **Metal binding and active site (D43, D110, E89)** One of the significant findings from this study is identification of amino acid residues involved in metal binding and catalysis. It is known from biochemical studies that endonuclease V is a metal-dependent DNA endonuclease (Huang, J., et al., Biochemistry 40(30):8738-48 (2001) and Yao, M., et al., J. Biol Chem 269(23):16260-08 (1994),

25    which are hereby incorporated by reference in their entirety). The enzyme is most active with $Mg^{2+}$ or $Mn^{2+}$ as the metal cofactor. Previous binding studies have demonstrated that a divalent metal ion is not only required for catalysis but also for formation of a stable enzyme-substrate complex (Huang, J., et al., Biochemistry 40(30):8738-48 (2001), which is hereby incorporated by reference in its entirety). For

30    many endonucleases, a few negatively charged amino acid residues, such as Asp and Glu, are involved in metal binding (Cao, W., et al., J Biol Chem 273(49):33002-10 (1998); Kim, D.R., et al., Genes Dev 13(23):3070-80 (1999) and Koval, R.A., et al.,

Curr Opin Chem Biol 3(5):578-83 (1999), which are hereby incorporated by reference in their entirety). Out of four such residues mutated, three of them (D43, D110, E89) appear important for coordinating metal ion(s). D43A and D110A abolish the endonuclease activities towards all substrates tested, which include double-stranded

5 and single-stranded inosine substrates (Figure 21) and double-stranded uracil and AP site substrates (Figure 26). E89A had substantially reduced catalytic activities. However, all three mutants retain wild-type binding affinity towards inosine substrates, indicating their important role in catalysis. Most interestingly, D43A and D110A, and in some case E89A, bind to inosine substrates in the absence of a metal

10 ion. D83A and E98A in restriction endonuclease MunI have shown a similar binding behavior (Laugnavicius, A., et al., Biochemistry 36(37):11086-92 (1997), which is hereby incorporated by refernce in its entirety). More recently, the MunI crystal structure complexed with cognate DNA positions D83A and E98A at the active site (Deibert, M., et al., Embo J 18(21):5805-16 (1999), which is hereby incorporated by

15 reference in its entirety). It is likely that D43 and D110 in Tma endo V, and possibly E89, are involved in binding catalytic metal(s) for the hydrolysis of the scissile phosphate bond. $Ca^{2+}$ competition has been used as a probe to assess the numbers of metal ions involved in DNA cleavage by EcoRV (Cao, W., et al., Biochim Biophys Acta 1546(1):253-60 (2001) and Vipond, I.B., et al., Biochemistry 34(2):697-704

20 (1995), which are hereby incorporated by reference in their entirety). A stimulatory effect by $Ca^{2+}$ on cognate site cleavage has been taken as an indication of two-metal catalytic mechanism. No enhancement of inosine cleavage was observed in $Ca^{2+}$-$Mg^{2+}$ competition. Thus, the number of metal ions involved in strand cleavage in endonuclease V remains to be determined.

25          **Y80** Alanine substitution at Y80 substantially reduced the affinity of endo V to the double- and single-stranded inosine substrate (Figures 22 and 25), as well as the nicked inosine product (Figure 23). Evidently, weak binding helps endo V dissociate from the product, thereby allowing rapid turnover of the inosine substrate (Figure 24). The loss of AP endonuclease and uracil endonuclease activities may also

30 be attributed to a weaker binding affinity (Figure 26). These results suggest that Y80 plays an important role in maintaining a stable complex between the enzyme and the repair-intermediate. Y80 may play such a role by making direct contact to the

substrate and the product through base contact or phosphate backbone interaction, or by organizing a network of contacts mediated by other amino acid residues. The kinetic property of accelerated product release is analogous to R177A in human AP endonuclease APE1 (Mol, C.D., et al., Nature 403(6768):451-56 (2000), which is hereby incorporated by reference in its entirety). In a DNA-bound structure, R177 makes a direct contact to the 3' phosphate at the AP site to lock APE1 onto the AP site (Mol, C.D., et al., Nature 403(6768):451-56 (2000), which is hereby incorporated by reference in its entirety). Thus, a phosphate backbone contact may contribute to tight product binding.

**R88 and H116** R88A and H116A exhibit similar properties. Both of these variants have reduced affinity to the double-stranded inosine substrate and nicked product (Figures 22-23), which results in a higher turnover (Figure 24). They maintain wt level single-stranded inosine cleavage activity (Figure 25). The major difference between R88A and H116A is at uracil substrates. H116A is about 9-fold more active than R88A for G/U substrate and 5-fold more active for T/U substrate (Figure 26). Apparently, R88 plays a more important role in uracil recognition.

**K139** Alanine substitution at K139 has little effect on binding (Figures 22-23, 25). K139A maintains wt level cleavage activity toward the double-stranded inosine substrate I/A (Figure 21). Similar to the wt enzyme, K139A remains bound even after cleaving inosine substrate due to tight product binding (Figure 24). The main effects of K139A substitution on endo V is at cleavage of non-inosine substrates. In addition to lack of AP endonuclease activity, K139A has a substantially reduced uracil endonuclease activity (Figure 26). A more detailed kinetic analysis is required to understand the precise catalytic role K139 may play with different substrates.

As the first step to elucidate the structural basis of endonuclease V catalytic and recognition mechanism, an alanine scanning mutagenesis was carried out at nine conserved positions of Tma endonuclease V. D43 and D110, along with E89 may coordinate metal ion(s) for the scissile phosphate bond hydrolysis and are part of the active site. Y80 makes substantial contribution to substrate and nicked product binding. While the lack of strong binding to substrate may account for loss of AP site and uracil cleavage activity, this same property also changes the kinetics of

cleaving inosine-containing substrates, such that the product release step is no longer rate limiting. R88A and H116A affect binding steps as well, resulting in diminishing endonuclease activities toward non-inosine substrates. The tight binding by K139A limits the turnover of inosine substrates. The lack of AP site and uracil cleavage

5    suggests that K139A may affect steps other than substrate or product binding. A full understanding of the mutational effects described here awaits determination of the endo V-DNA complex structure.

Generation of additional Tma endonuclease V mutants at the above mentioned positions revealed four of these variants (R88Q, R88E, H116Q, and

10    H116T) which preferentially nicked or cleaved at least one heteroduplexed DNA containing mismatched bases better than wild-type enzyme in selected buffer conditions. The R88Q and R88E enzymes demonstrated a stronger preference for cleaving the G base in both G:A and A:G mismatched substrate than wild-type endonuclease. The H116Q and H116T enzymes exhibited almost exclusive activity

15    towards "A" base containing substrates. There was almost no activity towards the "G" containing strand, suggesting these variant enzymes are proof of principle that stronger enzymes for specific mismatched sequences can be developed. Such enzymes will improve signal-to-noise in scoring of unknown mutations and polymorphisms, both in pooling experiments, and for mutations in difficult sequence

20    environments.

Although preferred embodiments have been depicted and described in detail herein, it will be apparent to those skilled in the relevant art that various modifications, additions, substitutions and the like can be made without departing from the spirit of the invention and these are therefore considered to be within the

25    scope of the invention as defined in the claims which follow.
